Features

Definition of Statistics

- The collection and storage of data, e.g. by statistical offices.
- The mathematical analysis of data, e.g. the calculation of measures and ratios, the estimation of unknown parameters, the testing of hypotheses

Descriptive Statistics

- Description of existing data by measures, tables, graphs.

Basic Terminology

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Inductive (or Inferential) Statistics

- Investigation of patterns and causes that are behind the data and (partially) explain the data.
- Exploratory data analysis: the goal is to generate hypotheses.
- Confirmatory data analysis: aim is to test existing theories, e.g. by estimating parameters or testing hypotheses.

Features and Scale Types

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Qualitative Features

- **binary** (yes/no). Example: EU citizenship.
- **categorical** (classification). Example: single/divorced/married/widowed.
- **ordinal** (rank). Example: Grades 1–5.

Quantitative Features

- **discrete** (integer). Example: counting.
- **continuous** (real-valued). Example: measuring process.

Features and Scale Types

Scale Types

- **Nominal Scale:** Numerical values are only designations for mutually exclusive categories.
- **Ordinal Scale:** Order of numbers is essential.
- **Interval Scale:** Order and differences between values are interpretable in a meaningful way, the zero point is arbitrarily fixed.
- **Ratio Scale:** Order, differences and ratios are meaningfully interpretable, there is an absolute zero point.

Features and Scale Types

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Example

- The marital status of a person is coded by numbers (1=single, 2=married, 3=divorced, 4=widowed). Nominal scale.
- A team's standing in the championship is indicated by its rank in the league. Ordinal scale.
- The years (2007, 2008, ...) form an interval scale, since the zero point is arbitrary.
- The Celsius scale of temperature is an interval scale, since the zero point is arbitrarily fixed.
- The Kelvin scale of temperature is a ratio scale, since the zero point is physically fixed.
- The height of a person is given in cm. A ratio scale, the zero value is natural.

Features and Scale Types

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional

Features

Example

The following data matrix D compiles several features of eight individuals.

Number	gender	age	education
1	1	34	2
2	2	54	1
3	2	46	3
4	1	27	4
5	1	38	2
6	1	31	3
7	2	48	4
8	2	51	2

Gender: 1=F, 2=M, Age: in years. Education: 1=compulsory school, 2=high school, 3=bachelor's, 4=master's.

Statements and Frequencies

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

The Concept of a Statement

- We call the set of objects of study the **population** Ω .
- A **statement** $A(x)$ is a statement about properties of the elements $x \in \Omega$.
- For each $x \in \Omega$, $A(x)$ must be either **true** or **false**.

Example

Let $A(x)$ be the statement “ x is female”. Then $A(1)$ is true and $A(2)$ is false.

Example

Let $B(x)$ be the statement “ x is over 50 years old”. Then $B(2)$ is true and $B(6)$ is false.

Statements and Frequencies

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Linking Statements

Let A and B be two statements.

Symbol	Name	Meaning
$A \cup B$	disjunction	A or B (or both)
$A \cap B$	conjunction	A and B (both A and B)
A'	negation	not A (the opposite of A)
$A \subseteq B$	implication	from A follows B

Statements and Frequencies

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Definition (Absolute Frequency)

Let $A(x)$ be a statement about $x \in \Omega$. The **absolute frequency** $h(A)$ of A is the number of elements of Ω for which $A(x)$ is true.

Example

If $A(x)$ is the statement “The person $x \in D$ has at least a bachelor’s degree”. Then $h(A) = 4$.

Statements and Frequencies

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Definition (Relative Frequency)

Let $A(x)$ be a statement about $x \in \Omega$. The **relative frequency** $f(A) = h(A)/n$ of A is the absolute frequency $h(A)$ divided by the total number $n = |\Omega| \in \mathbb{N}$ of elements.

Example

If $B(x)$ is the statement “The person $x \in D$ is older than thirty years”. Then $f(B) = 7/8$.

Statements and Frequencies

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Special Statements

- $A = \emptyset$: A is never true, $h(A) = f(A) = 0$.
- $A = \Omega$: A is always true, $h(A) = n, f(A) = 1$.

Arithmetic Laws for Frequencies

Addition Law

$$A \cap B = \emptyset \implies \begin{cases} h(A \cup B) = h(A) + h(B) \\ f(A \cup B) = f(A) + f(B) \end{cases}$$

Statements and Frequencies

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Basic Terminology

Features and Scale Types

Statements and Frequencies

One-dimensional Features

Two-dimensional
Features

Sieve Formula

$$h(A \cup B) = h(A) + h(B) - h(A \cap B)$$

Example

33% of a bank's customers have a home loan, 24% have a loan to finance consumer goods, 11% have both. What is the percentage of customers who have neither a housing loan nor a consumer goods loan?

Examples

Two-dimensional
Features

- The frequency distribution (histogram) can be smoothed with a kernel density estimator.
- The density of the observed feature is thereby approximated by a sum of kernels $K(\cdot)$:

$$\hat{f}(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right)$$

- h is the bandwidth of the kernel density estimator.
- A popular kernel is the Gaussian kernel:

$$K(x) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{x^2}{2}\right)$$

Examples

Two-dimensional
Features

- Data lists are often extensive enough that their content is to be summarized by a few empirical measures. Which measures are useful depends on the type of feature.
- Some measures start from the ordered data list $x_{(1)}, \dots, x_{(n)}$.
- We distinguish between measures of location, dispersion, and skewness.
- A measure of location (or position) indicates the value around which the data is concentrated.
- A measure of dispersion indicates how large the fluctuations of the data are around their central value.
- A skewness measure indicates how symmetrical the data are about their central value.

Measures of Location

Definition (Positional Measure)

Let $\mathbf{x} = (x_1, \dots, x_n)$ be a data list. The function $\ell(\mathbf{x})$ is called a position measure for \mathbf{x} if the following holds true:

- $\ell(a\mathbf{x} + b) = a\ell(\mathbf{x}) + b$
 - $\min(\mathbf{x}) \leq \ell(\mathbf{x}) \leq \max(\mathbf{x})$
-
- Meaningful position measures indicate the “typical” or “central” value of the data list.
 - Depending on the scale, different position measures may be meaningful.

Two-dimensional
Features

The Mean Value

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

- Meaningful for ordinal, interval and ratio scales.
- The mean minimizes the following function:

$$\bar{x} = \operatorname{argmin}_x \sum_{i=1}^n (x_i - x)^2$$

PYTHON: `xbar=np.mean(x)`

Empirical Measures

Boxplot and Empirical
Distribution Function

Examples

Two-dimensional
Features

Median of Data

$$\tilde{x} = x_{(n/2)}$$

- The median divides the ordered data list into two equal parts.
- Useful for ordinal, interval and ratio scales.
- The median minimizes the following function:

$$\tilde{x} = \operatorname{argmin}_x \sum_{i=1}^n |x_i - x|$$

PYTHON: `xmed=np.median(x)`

Kernel Density Estimator

Empirical Measures

Boxplot and Empirical
Distribution Function

Examples

Two-dimensional
Features

- The median is a special case of a more general term, the quantile.

α -quantile

$$Q_{\alpha} = x_{(\alpha n)}$$

- The α -quantile divides the ordered data list by the ratio $\alpha : 1 - \alpha$.

- Meaningful for ordinal, interval, and ratio scales.

 PYTHON: `qa=numpy.quantile(x,alpha)`

- Q_0 is the smallest value, Q_1 is the largest value in the data list. $Q_{0.5}$ is the median.
- The five **quartiles** $Q_0, Q_{0.25}, Q_{0.5}, Q_{0.75}, Q_1$ form the **five point summary** of the data list.

 PYTHON: `fps=numpy.quantile(x,[0,0.25,0.5,0.75,1])`

Distribution Function

Examples

Two-dimensional
Features

LMS (Least Median of Squares)

LMS value is the midpoint of the shortest interval containing $h = \lfloor n/2 \rfloor + 1$ data points

- The LMS value is very insensitive to erroneous or atypical data (“outliers”).
- The LMS value minimizes the following function:

$$\tilde{x} = \operatorname{argmin}_x \operatorname{med}_{i=1}^n (x_i - x)^2$$

- A related measure of position is the “shorth”, the mean of all data in the shortest interval containing h data points.

Empirical Measures

of Data Analysis

W. Waltenberger

Introduction

One-dimensional Features

Graphical Representation

Kernel Density Estimator

Empirical Measures

Boxplot and Empirical

Distribution Function

Examples

Two-dimensional
Features

Mode

Mode is the most common value of a data list

- Useful mainly for qualitative features.
- For quantitative features, the mode can be determined from the kernel density estimator.

PYTHON: `xmode=scipy.stats.mode(x)`

HSM (Half-sample mode)

- Determine the shortest interval containing $h = \lfloor n/2 \rfloor + 1$ data points.
- Repeat the process on the data in that interval until there are two data points left.
- The HSM value is the average of these last two data points.

Dispersion Measures

Definition (Measure of Dispersion)

Let $\mathbf{x} = (x_1, \dots, x_n)$ be a data list. A function $\sigma(\mathbf{x})$ is called a measure of dispersion for \mathbf{x} if the following holds:

- $\sigma(\mathbf{x}) \geq 0$
- $\sigma(a\mathbf{x} + b) = |a| \sigma(\mathbf{x})$
- Meaningful measures of dispersion quantify the deviation of the data from their central value.
- Measures of dispersion are invariant under a shift of the data.
- Different measures of dispersion are useful depending on the scale and use case.

Empirical Measures

Empirical Measures

Boxplot and Empirical
Distribution Function

Examples

Two-dimensional
Features

The Standard Deviation

$$s = \sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2}$$

- Useful for interval and ratio scales.
- The standard deviation has the same dimension as the data.
- The square of the standard deviation is called **variance of the data**.

 PYTHON: `xstd=numpy.std(x)`

 PYTHON: `xvar=numpy.var(x)`

Examples

Two-dimensional
Features

LoS (Length of the Shorth)

LoS is the length of the shortest interval containing
 $h = \lfloor n/2 \rfloor + 1$ data points

- Meaningful for ordinal, interval and ratio scales.

Skewness Measures

Definition (Measure of Skewness)

Let $\mathbf{x} = (x_1, \dots, x_n)$ be a data list. The function $\mathfrak{s}(\mathbf{x})$ is called a skewness measure for \mathbf{x} if the following holds:

- $\mathfrak{s}(a\mathbf{x} + b) = \text{sgn}(a) \mathfrak{s}(\mathbf{x})$
 - $\mathfrak{s}(\mathbf{x}) = 0$ if $\exists b : \mathbf{x} - b = b - \mathbf{x}$
- Sensible skewness measures quantify the asymmetry of the data.
 - Skewness measures are invariant under translation of the data.
 - Different skewness measures are useful depending on the scale.

The Skewness

$$\gamma = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^3}{s^3}$$

- The skewness γ is equal to 0 for symmetric data.
- If $\gamma < 0$, the data is said to be **skewed towards the left**.
- If $\gamma > 0$, the data is said to be **right skewed**.
- Useful for interval and ratio scales.

PYTHON: `xgamma=scipy.stats.skew(x)`

Skewness Coefficient

$$SK = \frac{R - L}{R + L}$$

where $R = Q_{0.75} - Q_{0.5}$, $L = Q_{0.5} - Q_{0.25}$.

- SK is between -1 ($R = 0$) and $+1$ ($L = 0$).
- The skewness coefficient is equal to 0 for symmetric data.
- If $SK < 0$, the data is called **left skewed**.
- If $SK > 0$, the data is called **right skewed**.
- Useful for ordinal, interval and ratio scales.

- The graphical representation of the cumulative frequencies is called the **empirical distribution function** of the data list.

Definition (Empirical Distribution Function)

The empirical distribution function $F_n(x)$ of the data list $\mathbf{x} = (x_1, \dots, x_n)$ is the proportion of the data that are less than or equal to x :

$$F_n(x) = f(\vec{x} \leq x).$$

- If $x_i \leq x < x_{i+1}$, then:

$$F_n(x) = f(x_1) + \dots + f(x_i).$$

- F_n is a step function. The step points are the data points, the step heights are the relative frequencies of the data points.

W. Waltenberger

Introduction

One-dimensional Features

Two-dimensional
Features

Qualitative Features

Quantitative Features

Correlations

- We first consider two binary features A and B .
- The frequency of the occurrence of A and B can be expressed in an **four-field table** or **contingency table**.

- example:

$A = \text{"The person is female"}$

$B = \text{"The person is a smoker"}$

- Four-field table for 1000 people:

	B	B'	
A	228	372	600
A'	136	264	400
	364	636	1000

Qualitative Features

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

One-dimensional Features

Two-dimensional
Features

Qualitative Features

Quantitative Features

Correlations

- General structure of a four-field table:

	B	B'	
A	$h(A \cap B)$	$h(A \cap B')$	$h(A)$
A'	$h(A' \cap B)$	$h(A' \cap B')$	$h(A')$
	$h(B)$	$h(B')$	n

- Row and column sums are the frequencies of the expressions A, A' and B, B' .

Qualitative Features

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

One-dimensional Features

Two-dimensional
Features

Qualitative Features

Quantitative Features

Correlations

- The four-field table can be converted to **relative frequencies** using division by n :

	B	B'	
A	$f(A \cap B)$	$f(A \cap B')$	$f(A)$
A'	$f(A' \cap B)$	$f(A' \cap B')$	$f(A')$
	$f(B)$	$f(B')$	1

- row and column sums are the relative frequencies of the expressions A, A' and B, B' .

Qualitative Features

- The correlation of the two features can be measured by **four-field correlation**:

Four-field Correlation

$$\rho(A, B) = \frac{f(A \cap B) - f(A)f(B)}{\sqrt{f(A)f(A')f(B)f(B')}}}$$

- It is always true: $-1 \leq \rho(A, B) \leq 1$
- If $\rho(A, B) > 0$, A and B are called **positively coupled**.
- If $\rho(A, B) < 0$, A and B are called **negatively coupled**.

Qualitative Features

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

One-dimensional Features

Two-dimensional
Features

Qualitative Features

Quantitative Features

Correlations

- The sign of $\rho(A, B)$ indicates the **direction** of the coupling.
- The magnitude of $\rho(A, B)$ indicates the **strength** of the coupling.
- Specifically:

$$A = B \implies \rho(A, B) = 1$$

$$A = B' \implies \rho(A, B) = -1$$

- An existing coupling is no proof of a causal relationship!
- The coupling can also result from a common cause for both features.

Properties of scatter plot

- (\bar{x}, \bar{y}) is the center of the point cloud.
 - The projection of the scatter plot onto the x -axis results in the scatter plot of the data list x_1, \dots, x_n .
 - The projection of the point cloud onto the y -axis results in the scatter plot of the data list y_1, \dots, y_n .
-
- From the scatter plot of dataset 4, it can be seen that **tendentially** larger height is associated with larger weight.
 - There is obviously a relationship between the two features x and y , which intuitively is very obvious.

Correlations

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

One-dimensional Features

Two-dimensional
Features

Qualitative Features

Quantitative Features

Correlations

- We need a **measure** for this notion of correlation.
- A useful measure is the **empirical correlation coefficient**.
- Let $(x_1, y_1), \dots, (x_n, y_n)$ be a bivariate sample.
- We compute the **standard scores**:

$$z_{x,i} = \frac{x_i - \bar{x}}{s_x}, \quad z_{y,i} = \frac{y_i - \bar{y}}{s_y}$$

- We recall that

$$s_x^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \quad \text{and} \quad s_y^2 = \frac{1}{n} \sum_{i=1}^n (y_i - \bar{y})^2$$

- The empirical correlation coefficient is the **mean of the products** of the standard scores.

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

- The specific outcome of an experiment generally cannot be accurately predicted; however, the possible outcomes are known.
- Several reasons:
 - The observed objects are a random selection (sample) from a larger population.
 - The observed process is fundamentally indeterministic (quantum mechanics).
 - The observed process is practically indeterministic: lack of knowledge of the initial state (roulette), chaotic system (hydrodynamics, psychology).
- In addition, measurement errors can add stochasticity (randomness) to the result.

Introduction

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

- The goal of probability theory is to assign **probabilities** to sets of outcomes, called events.
- Two interpretations of probabilities exist.

Introduction

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Frequentist Interpretation

- The probability of an event is its frequency, if the experiment repeat often enough, under the same conditions.
- The statistics based on this interpretation is called 'frequentist'.

Example

The probability of the output '1' when rolling a dice is the limit of the frequency for a large number of rolls.

Subjective Interpretation

- The probability of an output is a statement about the belief of the person giving the probability.
- The statistics based on this interpretation is called 'Bayesian'.

Example

'The probability that it will rain tomorrow is 40 percent' is a statement about the belief of the person making this statement.

Introduction

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

- In practice, the transition between the two approaches is often fluid.
- In many cases the results are identical, only the interpretation is different.
- The Bayesian approach is more comprehensive and flexible.
- The frequentist approach is often simpler, but more limited. Its interpretation is typically clearer.

W. Waltenberger

Introduction

Events

The Sample Space

The Event Algebra

Repeating Experiments

Probabilities

Conditional Probability

Definition (Event)

An **event** E is a subset of the sample space Ω . An event E **occurs** if E contains the outcome $\omega \in \Omega$ of the experiment.

Example

The roll of a dice has the sample space $\Omega = \{1, 2, 3, 4, 5, 6\}$. The event E (even number) is the subset

$$E = \{2, 4, 6\}$$

E occurs when an even number is thrown.

The Event Algebra

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

The Sample Space

The Event Algebra

Repeating Experiments

Probabilities

Conditional Probability

Definition (event algebra)

The set of all events of the sample space Ω is called the event algebra $\Sigma(\Omega)$.

- In the finite or countably infinite case, **any** subset can be considered as an event. The event algebra is called **discrete**.
- In the uncountably infinite case, certain pathological (non-measurable) subsets must be excluded. The event algebra is called **continuous** or **real-valued**.
- Like statements, two events $A \in \Sigma$ and $B \in \Sigma$ can be logically **connected**.

The Event Algebra

W. Waltenberger

Introduction

Events

The Sample Space

The Event Algebra

Repeating Experiments

Probabilities

Conditional Probability

- With these operators, Σ is a **Boolean algebra**: distributive complementary lattice with zero- and one-elements.
- The null element $\mathbf{0} = \emptyset$ is the **impossible event**.
- The one element $\mathbf{1} = \Omega$ is the **sure event**.
- An event consisting of only one possible result is called an **elementary event**.

The Event Algebra

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

The Sample Space

The Event Algebra

Repeating Experiments

Probabilities

Conditional Probability

- If Ω is (countably or uncountably) infinite, one requires that also countably many unions and intersections of events can be formed.
- The event algebra is then a so-called σ -algebra.
- If in the continuous case $\Omega = \mathbb{R}$, then the event algebra $\Sigma(\Omega)$ is the smallest σ -algebra containing all intervals.

Subsection: Repeating Experiments

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

The Sample Space

The Event Algebra

Repeating Experiments

Probabilities

Conditional Probability

4 Introduction

5 Events

- The Sample Space
- The Event Algebra
- Repeating Experiments

6 Probabilities

7 Conditional Probability

Repeating Experiments

- The sample space of a dice roll is

$$\Omega = \{1, 2, 3, 4, 5, 6\}$$

Consequently, the event algebra $\Sigma(\Omega)$ has six elementary events:

$$e_1 = \{1\}, e_2 = \{2\}, e_3 = \{3\}, e_4 = \{4\}, e_5 = \{5\}, e_6 = \{6\}$$

and a total of $2^6 = 64$ events (subsets of Ω).

- The sample space of a double roll is the Cartesian product $\Omega \times \Omega$:

$$\Omega \times \Omega = \{(i, j) | i, j = 1, \dots, 6\}$$

The ordered pair (i, j) means i on the first throw, j on the second throw. Consequently, the event algebra $\Sigma(\Omega \times \Omega)$ has 36 elementary events e_{ij} :

$$e_{11} = \{(1, 1)\}, \dots, e_{36} = \{(6, 6)\}$$

Repeating Experiments

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

The Sample Space

The Event Algebra

Repeating Experiments

Probabilities

Conditional Probability

- Similarly, in the case of rolling n times, the sample space is n times the Cartesian product $\Omega \times \Omega \times \dots \times \Omega$.

Example (event algebra of double throw)

Examples of events in the event algebra of the double roll are:

6 on the first throw: $\{(6, 1), (6, 2), \dots, (6, 6)\}$

6 on the second throw: $\{(1, 6), (2, 6), \dots, (6, 6)\}$

Both throws equal: $\{(1, 1), (2, 2), \dots, (6, 6)\}$

Sum of throws equal to 7: $\{(1, 6), (2, 5), \dots, (6, 1)\}$

Repeating Experiments

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

The Sample Space

The Event Algebra

Repeating Experiments

Probabilities

Conditional Probability

Example (Repeated Bernoulli Experiment)

An experiment that has only two possible outcomes is called a **Bernoulli experiment** or **alternative experiment**. There are two outcomes, 1 (“success”) and 0 (“failure”).

An alternative experiment that is executed n times is described by a sample space with 2^n possible outcomes, namely all sequences of the form (i_1, \dots, i_n) with $i_j = 0$ or 1.

Often, however, only the **frequency** of the occurrence of 1 (or 0) is of interest. This situation is more comprehensively described by only $n + 1$ outcomes: 1 occurring 0, 1, 2, ... or n times. If the event E_1 denotes a single occurrence of 1, then E_1 is the union of multiple elementary events of the original event algebra:

$$E_1 = \{(e_1, e_0, \dots, e_0), (e_0, e_1, e_0, \dots, e_0), \dots, (e_0, \dots, e_0, e_1)\}$$

An example is an n -fold coin flip.

Probabilities

Probability Measures

Law of Large Numbers

Conditional Probability

Definition (probabilitymeasure)

Let Σ be an event algebra, A and B events in Σ , and P a mapping from Σ into \mathbb{R} . P is called a **probability measure** if the following holds:

1. positivity $P(A) \geq 0, \forall A \in \Sigma$
2. additivity: $A \cap B = \mathbf{0} \implies$
 $P(A \cup B) = P(A) + P(B)$
3. normalization $P(\mathbf{1}) = 1$

Probability Measures

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Probability Measures

Law of Large Numbers

Conditional Probability

Definition (probability space)

If Σ is a σ -algebra, which must be assumed for infinite event spaces, one requires for countable J :

$$4. \sigma\text{-additivity: } A_i \in \sigma, i \in J; A_i \cap A_j = \emptyset, i \neq j \implies \\ P\left(\bigcup_{i \in J} A_i\right) = \sum_{i \in J} P(A_i)$$

Σ is then called normalized, and (Σ, P) a **probability space**. P is also called a **probability distribution**.

Probability Measures

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Probability Measures

Law of Large Numbers

Conditional Probability

Calculating laws for probability

If (Σ, P) is a probability space, then:

- $P(\mathbf{0}) = 0$
- $P(\mathbf{1}) = 1$
- $0 \leq P(A) \leq 1, \forall A \in \Sigma$
- $P(A') = 1 - P(A), \forall A \in \Sigma$
- $A \subseteq B \implies P(A) \leq P(B), \forall A, B \in \Sigma$
- $P(A \cup B) = P(A) + P(B) - P(A \cap B), \forall A, B \in \Sigma$
- If Σ has at most countably many elementary events $\{e_i \mid i \in I\}$, then $\sum_{i \in I} P(e_i) = 1$.

Probability Measures

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Probability Measures

Law of Large Numbers

Conditional Probability

- In a discrete event algebra, the probability of an event is equal to the sum of the probabilities of the elementary events whose union it is.
- Therefore, in this case, a probability measure is **uniquely determined** by the values it assigns to the elementary events.
- On the other hand, any positive function defined on the set of elementary events that satisfies the normalization condition can be uniquely continued to a probability measure.
- Thus, one can define infinitely many distributions on a discrete event algebra Σ .

Probability Measures

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Probability Measures

Law of Large Numbers

Conditional Probability

- In a continuous event algebra, the probability of each elementary event is 0.
- Therefore, the probability of an event can no longer be determined by summation.
- Instead, a **density function** $f(x)$ is given which assigns a nonnegative value $f(x)$ to each elementary event x .
- The probability of an event A is determined by **integration** over the density:

$$P(A) = \int_A f(x) \, dx$$

- The density function is **normalized** to 1:

$$\int_{\mathbb{R}} f(x) \, dx = 1$$

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- We now consider two events A and B that can occur in an experiment.
- **Question:** Is there a relationship between the events?
- Such a connection is called a **coupling**.
- **Positive Coupling:** The more often A occurs, the more often B tends to occur.
- **Negative Coupling:** The more often A occurs, the less often B also tends to occur.
- We can quantify the meanings of 'often' and 'rarely' with the frequency table.

Coupling and Conditional Probability

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- The frequency of the occurrence of A and B can be summarized in a **four-field table** or **contingency table**.

- Example:

$A = \text{'The person under study is female'}$

$B = \text{'The person under study has diabetes'}$

- Four-field table for 1000 persons:

	B	B'	
A	19	526	545
A'	26	429	455
	45	955	1000

Coupling and Conditional Probability

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- **Ordinary relative frequencies** are relative to the size n of the entire data set:

$$f(A \cap B) = \frac{h(A \cap B)}{n}$$

- **Conditional relative frequencies** are relative to the occurrence of the other feature:

$$f(A|B) = \frac{h(A \cap B)}{h(B)} = \frac{f(A \cap B)}{f(B)}$$

- $f(A|B)$ is called the conditional relative frequency of A given B .

Coupling and Conditional Probability

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- The four-field table results in the following conditional relative frequencies:

$$f(A|B) = \frac{19}{45} = 0.422, \quad f(A|B') = \frac{526}{955} = 0.551$$

- Thus, it can be assumed that the two features are coupled.
- $f(A|B) > f(A)$ indicates a positive coupling, $f(A|B) < f(A)$ indicates a negative coupling.

Coupling and Conditional Probability

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- If the data originate from a random experiment, then combinations of events can also be assigned probabilities.
- Probability table:

	B	B'	
A	$P(A \cap B)$	$P(A \cap B')$	$P(A)$
A'	$P(A' \cap B)$	$P(A' \cap B')$	$P(A')$
	$P(B)$	$P(B')$	1

- By the empirical law of large numbers, these probabilities are the limits of the respective relative frequencies.

Coupling and Conditional Probability

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- The conditional relative frequencies converge towards a limit with $n \rightarrow \infty$:

$$f_n(A|B) = \frac{f_n(A \cap B)}{f_n(B)} \rightarrow P(A|B) = \frac{P(A \cap B)}{P(B)}$$

Definition (Conditional probability)

$$P(A|B) = \frac{P(A \cap B)}{P(B)}$$

is called the **conditional probability of A under condition B** , provided that $P(B) \neq 0$.

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

Example (The symmetric cube)

If the cube is completely symmetric, the elementary events $e_i = \{i\}$ are assigned equal probabilities:

$$P(e_i) = \frac{1}{6}, \quad 1 \leq i \leq 6$$

We define the following events:

$$O = \{1, 3, 5\}, \quad E = \{2, 4, 6\}$$

Then for example

$$P(e_1|O) = \frac{P(e_1 \cap O)}{P(O)} = \frac{P(e_1)}{P(O)} = \frac{1}{3}$$

$$P(e_1|E) = \frac{P(e_1 \cap E)}{P(E)} = \frac{P(\emptyset)}{P(E)} = 0$$

Coupling and Conditional Probability

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

Definition (Decomposition)

The events B_1, B_2, \dots, B_m form a **decomposition** of the sample space Ω if the following holds:

- 1 Non-overlapping: $B_i \cap B_j = \emptyset, i \neq j$
- 2 Completeness: $B_1 \cup B_2 \cup \dots \cup B_m = \Omega$

Theorem

If the events B_1, B_2, \dots, B_m form a decomposition of the sample space Ω , it follows that:

$$P(B_1) + P(B_2) + \dots + P(B_m) = P(\Omega) = 1$$

Bayes' Theorem

4 Introduction

5 Events

6 Probabilities

7 Conditional Probability

- Coupling and Conditional Probability
- Bayes' Theorem
- Independence

Independence

- Two events are **positively coupled** if

$$P(A|B) > P(A) \quad \text{or} \quad P(A \cap B) > P(A)P(B)$$

- Two events are **negatively coupled** if

$$P(A|B) < P(A) \quad P(A \cap B) < P(A)P(B)$$

- If neither positive nor negative coupling is present, then A and B are mutually **independent**.

Independence

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

Definition (Independence)

Two events A and B are called **stochastically independent** if

$$P(A \cap B) = P(A)P(B)$$

The events A_1, A_2, \dots, A_n are called independent if:

$$P(A_1 \cap \dots \cap A_n) = P(A_1) \cdot \dots \cdot P(A_n)$$

For $n > 2$, pairwise independence of any two events A_i and A_j is not generally sufficient!

Example

We consider flipping a fair coin twice (heads H /tails T). The possible outcomes are $\Omega = \{HH, HT, TH, TT\}$. We define the events:

$$E_1 = \{HH, HT\} \dots \text{head on first throw}$$

$$E_2 = \{HH, TH\} \dots \text{head on second throw}$$

$$E_3 = \{HH, TT\} \dots \text{even number of heads}$$

Then, for all $i \neq j$:

$$P(E_i \cap E_j) = \frac{1}{4} = P(E_i) \cdot P(E_j)$$

but

$$P(E_1 \cap E_2 \cap E_3) = \frac{1}{4} \neq \frac{1}{8} = P(E_1) \cdot P(E_2) \cdot P(E_3)$$

Independence

- If A and B are independent, then $P(A|B) = P(A)$ and $P(B|A) = P(B)$.
- The four-field table for two independent events:

	B	B'	
A	$P(A)P(B)$	$P(A)P(B')$	$P(A)$
A'	$P(A')P(B)$	$P(A')P(B')$	$P(A')$
	$P(B)$	$P(B')$	1

- The coupling can be measured by the **four-field correlation**:

Four-field Correlation

$$\rho(A, B) = \frac{P(A \cap B) - P(A)P(B)}{\sqrt{P(A)P(A')P(B)P(B')}}}$$

Properties of Four-field Correlation

- $-1 \leq \rho(A, B) \leq 1$
- $\rho(A, B) = 0 \iff A \text{ and } B \text{ independent}$
- $\rho(A, B) > 0 \iff A \text{ and } B \text{ positively coupled}$
- $\rho(A, B) < 0 \iff A \text{ and } B \text{ negatively coupled}$

Independence

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- The sign of $\rho(A, B)$ indicates the **direction** of the coupling.
- The magnitude of $\rho(A, B)$ indicates the **strength** of the coupling.
- Specifically:

$$A = B \implies \rho(A, B) = 1$$

$$A = B' \implies \rho(A, B) = -1$$

- An existing coupling is no proof for a causal relationship!
- The coupling can also result from a common cause for both events.

Independence

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

- Two events can be considered independent if there is no connection whatsoever between them. The occurrence of one event cannot affect the probability of the other.
- Two elementary events are never independent, since their \cap -connection is always the impossible event.
- Two elementary events are even highly 'mutually dependent' since the occurrence of one precludes the occurrence of the other with complete certainty.
- If E_1 and E_2 are two independent events of a probability space (Σ, P) , then E_1 and E'_2 , E'_1 and E_2 , and E'_1 and E'_2 are also independent.

Independence

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

Example (rolls with two distinguishable dice)

There are 36 elementary events $e_{ij} = \{(i, j)\}$, $1 \leq i, j \leq 6$. The event E_i^1 of rolling an i on the first roll is thus composed of:

$$E_i^1 = e_{i1} \cup e_{i2} \cup \dots \cup e_{i6} \text{ and analogously}$$

$$E_j^2 = e_{1j} \cup e_{2j} \cup \dots \cup e_{6j}$$

Clearly, $E_i^1 \cap E_j^2 = e_{ij}$.

If we can assume that all elementary events are **equally probable**, then:

$$P(E_i^1) = \frac{1}{6}, \quad P(E_j^2) = \frac{1}{6}$$

$$P(E_i^1 \cap E_j^2) = P(e_{ij}) = \frac{1}{36} = P(E_i^1) \cdot P(E_j^2)$$

Independence

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

Example (Continuation)

Thus, in this case, the elementary events of the simple throw are also **equally probable** and the two partial throws are **independent**.

Conversely, if we assume that for both partial throws the elementary events are equally probable, and that E_i^1 and E_j^2 are independent for all i and j , then the e_{ij} are equally probable.

If the partial rolls are not independent, then the e_{ij} **are no longer** equally probable, **despite** e_i and e_j being equally probable! An example of this is the 'rolling' a very large dice, which can be rotated by a mere 90° each time. E.g. the elementary event e_{34} is then no longer possible and must therefore be assigned a probability of 0.

Independence

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Events

Probabilities

Conditional Probability

Coupling and Conditional
Probability

Bayes' Theorem

Independence

Example (Repetition of an alternative experiment)

The event algebra has 2^n elementary events, namely sequences of the form (i_1, \dots, i_n) , $i_j = 0$ or 1 . If the repetitions are independent, and p denotes the probability of 1 occurring, the probability of a sequence

$$P(\{(i_1, \dots, i_n)\}) = p^{n_1} (1 - p)^{n_0}$$

where n_0 or n_1 denotes the number of occurrences of 0 or 1, respectively. Clearly, $n_0 + n_1 = n$.

Definition (Random Variable)

A mapping X :

$$\omega \in \Omega \mapsto x = X(\omega) \in \mathbb{R}$$

that assigns a real number to each element ω of the sample space Ω is called a (one-dimensional or univariate) **random variable**.

- If Ω is finite or countably infinite, any mapping X is allowed.
- If Ω is uncountably infinite, X must be a **measurable** mapping.
- Since the value of a random variable depends on the outcome of the experiment, we can assign probabilities to the possible values.

Random Variables

Basic Terms

Discrete Random Variable

Continuous Random Variable

Independence

Convolution

Moments

Functions of Random
Samples

- If the random variable X takes only finitely or countably infinitely many values, it is called **discrete**.
- If the random variable X takes a continuum of values, it is called **continuous** or **real-valued**.

Example

The mapping that assigns the number of eyes i to the elementary event e_i when rolling the dice is a discrete random variable. Of course, the mapping $e_i \mapsto 7 - i$ would also be a discrete random variable.

Example

The mapping assigning a lifetime x to the decay of a particle is a continuous random variable.

Definition (Continuous density function)

If F_X is differentiable, X is called a **continuous random variable**. For the distribution of X , according to the main theorem of integral calculus:

$$P_X(x_1 < X \leq x_2) = F_X(x_2) - F_X(x_1) = \int_{x_1}^{x_2} f_X(x) dx$$

where $f_X(x) = F'_X(x)$. The derivative of the distribution function, the function f_X , is called the **probability density function** or, again, the density of X for short.

- The probability measure P_X is called the distribution of X . It is defined on an event algebra Σ consisting of sets of real numbers and containing at least all intervals and their unions as elements.
- In analogy with discrete random variables, the probability P_X of a set $M \in \Sigma$ can be easily specified using density:

$$P_X(M) = \int_M f_X(x) \, dx$$

- The probability of a single point is always equal 0:

$$P_X(\{x\}) = \int_x^x f_X(x) \, dx = 0$$

Random Variables

Basic Terms

Discrete Random Variable

Continuous Random Variable

Independence

Convolution

Moments

Functions of Random
Samples

- Therefore

$$P_X((x_1, x_2]) = P_X((x_1, x_2)) = P_X([x_1, x_2]).$$

- More generally, a statement about continuous random variables is obtained by replacing summation with integration in a statement about discrete random variables.
- E.g. for a discrete density f :

$$\sum_{k \in \mathbb{N}_0} f(k) = 1$$

similarly, for a continuous density f :

$$\int_{-\infty}^{\infty} f(x) \, dx = 1$$

Important continuous distribution families

- Normal distribution $\text{No}(\mu, \sigma^2)$
- Gamma distribution $\text{Ga}(a, b)$, with the special cases
 - Exponential distribution $\text{Ex}(\tau)$
 - Chisquare distribution $\chi^2(n)$
- Student's or t-distribution $t(n)$
- Beta distribution $\text{Be}(a, b)$
- Uniform distribution $\text{Un}(a, b)$

Definition (Independent Random Variable)

Two random variables X and Y are called independent if for all pairs (A, B) of events:

$$P(X \in A \cap Y \in B) = P_X(A) \cdot P_Y(B)$$

Definition (Joint Distribution Function)

The joint distribution function F_{XY} of X and Y is defined by

$$F_{XY}(x, y) = P(X \leq x \cap Y \leq y)$$

Definition (Common Density)

If X and Y are discrete random variables, their joint density is defined by:

$$f_{XY}(x, y) = P(X = x \cap Y = y)$$

If X and Y are continuous random variable, their joint density is defined by

$$f_{XY}(x, y) = \frac{\partial^2 F_{XY}}{\partial x \partial y}$$

Theorem

Two random variables X and Y are independent if and only if their joint distribution function is the product of their individual distribution functions:

$$F_{XY}(x, y) = F_X(x) \cdot F_Y(y)$$

Theorem

Two random variables X and Y are independent if and only if their joint density is the product of their individual density functions:

$$f_{XY}(x, y) = f_X(x) \cdot f_Y(y)$$

Definition (Convolution)

Let X and Y be two **independent** random variables and $Z = X + Y$ be their sum. The distribution of Z is called the **convolution** of the distributions of X and Y .

Example

An experiment measures the lifetime X of an unstable particle, with a measurement error Y . If X and Y are independent, the distribution of the observation $Z = X + Y$ is the convolution of the distributions of X and Y , respectively.

Theorem

Let X and Y be two **independent** random variables and $Z = X + Y$ be their sum. Then the density of Z is the **convolution product** of the densities of X and Y .

- If X and Y are discrete, then:

$$f_Z(n) = \sum_k f_X(n - k) f_Y(k)$$

- If X and Y are continuous, then:

$$f_Z(z) = \int_{\mathbb{R}} f_X(z - y) f_Y(y) \, dy$$

It should be noted that the effective integration range may depend on z .

Moments

Expectation

Variance

Skewness

Error Propagation

Functions of Random
Samples

Definition (Expectation)

Let X be a (discrete or continuous) random variable with density $f(x)$. Further, let g be any continuous real- or complex-valued function. Let $E_X[g] = E[g(X)]$ be defined by:

$$E[g(X)] = \sum_{k \in \mathbb{N}_0} g(k)f(k) \quad \text{or} \quad E[g(X)] = \int_{-\infty}^{\infty} g(x)f(x) dx$$

$E_X[g] = E[g(X)]$ is called the **expectation** of $g(X)$.

Expectation

Statistical Methods
of Data Analysis

W. Waltenberger

Random Variables

Moments

Expectation

Variance

Skewness

Error Propagation

Functions of Random
Samples

Definition (expectation of random variables)

If $g(x) = x$, then $E[g(X)] = E[X]$ is called the **expectation** or the **mean** of X .

$$E[X] = \int_{-\infty}^{\infty} x f(x) dx \text{ but } E[X] = \sum_{k \in \mathbb{N}_0} k f(k)$$

Properties of the Expectation

- $E[c] = c, c \in \mathbb{R}$
- $E[aX + b] = aE[X] + b$
- $E[X_1 + X_2] = E[X_1] + E[X_2]$
- X_1 and X_2 independently $\implies E[X_1 X_2] = E[X_1] \cdot E[X_2]$

Expectation

Statistical Methods
of Data Analysis

W. Waltenberger

Random Variables

Moments

Expectation

Variance

Skewness

Error Propagation

Functions of Random
Samples

- The expectation is a **location parameter**.
- The expectation may not exist. An example is the Cauchy distribution with the density

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad x \in \mathbb{R}$$

In this case, the median is a suitable location parameter.

Expectation

Statistical Methods
of Data Analysis

W. Waltenberger

Random Variables

Moments

Expectation

Variance

Skewness

Error Propagation

Functions of Random
Samples

Definition (moments)

Let X be a random variable. The expectation of $g(x) = (x - a)^k$, if it exists, is called **k -th moment of X around a** . The k -th moment around 0 is denoted by μ'_k . The k -th moment around the expected value $E[X]$ is called **central moment** μ_k .

- The expectation is the first moment around 0.
- The central moments μ_1, \dots, μ_k can be calculated from the moments around 0 μ'_1, \dots, μ'_k , and vice versa.
- Even if all moments of a distribution exist, it is still **not** uniquely determined.

Functions of Random
Samples

8 Random Variables

9 Moments

- Expectation
- **Variance**
- Skewness
- Error Propagation

10 Functions of Random Samples

Definition (Variance)

The second central moment μ_2 is called the **variance** of X , denoted by $\text{var}[X]$. The root of the variance is called the **standard deviation** of X , denoted by $\sigma[X]$.

- The standard deviation is a scale parameter that describes the width of the distribution.
- The standard deviation has the same dimension as the values of the random variables.
- Variance and standard deviation are (like all central moments) invariant against translations.
- The variance may not exist. An example is the distribution with density

$$f(x) = \frac{1}{(2 + x^2)^{3/2}}, \quad x \in \mathbb{R}$$

Variance

Statistical Methods
of Data Analysis

W. Waltenberger

Random Variables

Moments

Expectation

Variance

Skewness

Error Propagation

Functions of Random
Samples

Properties of the Variance

- $\text{var}[X] = \text{E}[X^2] - (\text{E}[X])^2$
- $\text{var}[aX + b] = a^2 \text{var}[X]$
- For independent X_1, \dots, X_n :

$$\text{var} \left[\sum_{i=1}^n X_i \right] = \sum_{i=1}^n \text{var}[X_i]$$

- Expectation
- Variance
- **Skewness**
- Error Propagation

10 Functions of Random Samples

Definition (Skewness)

The reduced third central moment $\gamma = \mu_3/\sigma^3$ is called the **skewness**.

- The skewness measures the asymmetry of a distribution. If the skewness is positive (negative), the distribution is called right skewed (left skewed). For symmetric distributions, it is 0.

Definition (Kurtosis)

The reduced fourth central moment $\kappa = \mu_4/\sigma^4$ is called the **curvature** or **kurtosis**.

- The kurtosis of the normal distribution is 3.
- Distributions with higher kurtosis have more pronounced tails than distributions with lower kurtosis.

Affine Transformations

- Let X be a random variable with density $f(x)$ and $Y = aX + b$.
- Then the density $g(y)$ of Y is equal to

$$g(y) = \frac{1}{|a|} f\left(\frac{y-b}{a}\right)$$

- Furthermore,

$$\begin{aligned} \mathbb{E}[Y] &= a\mathbb{E}[X] + b \\ \text{var}[Y] &= a^2 \text{var}[X] \\ \gamma[Y] &= \text{sgn}(a)\gamma[X] \\ \kappa[Y] &= \kappa[X] \end{aligned}$$

Error Propagation

of Data Analysis

W. Waltenberger

Random Variables

Moments

Expectation

Variance

Skewness

Error Propagation

Functions of Random
Samples

Nonlinear Transformations

- Let X be a random variable with density $f(x)$ and $Y = h(X)$.
- If $h(x)$ is bijective, the density $g(y)$ of Y is equal to

$$g(y) = \left| \frac{dh^{-1}}{dy} \right| f(h^{-1}(y))$$

- The expectation and variance of $Y = h(X)$ can be calculated **approximately** using the Taylor expansion of $h(x)$.

Error Propagation

Statistical Methods
of Data Analysis

W. Waltenberger

Random Variables

Moments

Expectation

Variance

Skewness

Error Propagation

Functions of Random
Samples

- Expanding around x_0 , the linear approximation reads

$$h(x) \approx h(x_0) + h'(x_0)(x - x_0)$$

- With a choice of $x_0 = E[X]$ we obtain

Theorem

$$E[h(X)] \approx h(E[X])$$

$$\text{var}[h(X)] \approx h'(E[X])^2 \cdot \text{var}[X] \quad (\text{linear error propagation})$$

- If the expansion is extended to the 2nd order, the improved approximation reads:

Theorem

$$E[h(X)] \approx h(E[X]) + \frac{1}{2}h''(E[X]) \cdot \text{var}[X]$$

- A point estimator is a sample function designed to provide as accurate an approximation as possible for an unknown distribution parameter ϑ :

$$T = g(X_1, \dots, X_n)$$

- The function $g(x_1, \dots, x_n)$ is called the estimator.
- The construction of sensible point estimators for a parameter ϑ is the central task of estimation theory.
- Many point estimators are conceivable for a parameter ϑ . However, a 'good' point estimator should meet certain requirements.

Definition (Bias)

A point estimator T for the parameter ϑ is called **unbiased** if for all values of ϑ :

$$E_{\vartheta}[T] = \vartheta$$

T is called **asymptotically unbiased** if:

$$\lim_{n \rightarrow \infty} E_{\vartheta}[T] = \vartheta$$

- If the unknown parameter is ϑ , then the expectation of the point estimator is equal to ϑ .
- An unbiased point estimator has random deviations from the true value ϑ , but no systematic bias.

The Normal Distribution $\text{No}(\mu, \sigma^2)$

- The **normal distribution** is one of the most important families of distributions in science and engineering. We denote it by $\text{No}(\mu, \sigma^2)$.
- Its density is:

$$f_{\text{No}}(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

- The normal distribution with $\mu = 0$, $\sigma = 1$ is called **standard normal distribution**. Its density is often denoted as $\varphi(x)$.
- Its distribution function $\Phi(x)$ can not be written in closed form.
- The mode M (the maximum of the density function) and the median m are at $x = \mu$.

The moments and CF of the normal distribution

Let $X \sim \text{No}(\mu, \sigma^2)$. Then:

- $E[X] = \mu$
 - $\text{var}[X] = \sigma^2$
 - $\gamma[X] = 0$
 - $\kappa[X] = 3$
-
- The α quantile of the standard normal distribution is denoted by z_α .
 - The α quantile of $\text{No}(\mu, \sigma^2)$ is equal to $\mu + \sigma z_\alpha$.

- One of the reasons for why the normal distribution is so important, is the **central limit theorem**. In its simplest formulation it reads:

Central Limit Theorem

Let X_1, \dots, X_n be a sample from the distribution F with mean μ and variance σ^2 . Then the distribution of

$$U_n = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}}$$

for $n \rightarrow \infty$ converges to the standard normal distribution.

- Clearly, if F is a normal distribution, then U_n is exactly standard normally distributed for all n .

Definition (Standard Score)

Let X be a normally distributed random variable with mean μ and variance σ^2 . Then

$$Z = \frac{X - \mu}{\sigma}$$

is the **standard score** of X .

Theorem

If X is normally distributed, then the standard score Z is standard-normally distributed.

Digression: The χ^2 distribution $\chi^2(n)$

- The density of the $\chi^2(n)$ distribution with n degrees of freedom is:

$$f_{\chi^2}(x; n) = \frac{1}{2^{n/2} \Gamma(\frac{n}{2})} x^{n/2-1} e^{-x/2} \cdot I_{[0, \infty)}(x)$$

- It is the gamma distribution $\text{Ga}(n/2, 2)$.
- The $\chi^2(2)$ distribution is the exponential distribution $\text{Ex}(2)$.
- The mode of the density is at $x = \max(n - 2, 0)$.
- The density of the $\chi^2(1)$ distribution has a pole at $x = 0$.
- For $n \rightarrow \infty$, the $\chi^2(n)$ distribution converges to the normal distribution $\text{No}(n, 2n)$.
- If X_1, \dots, X_n are independent and standard normally distributed, then $Y = \sum_{i=1}^n X_i^2$ is $\chi^2(n)$ -distributed with n degrees of freedom.

Theorem

Let X_1, \dots, X_n be a sample from the normal distribution $N(\mu, \sigma^2)$ and \tilde{X} be the sample median. Then:

- $E[\tilde{X}] = \mu$
- $\text{var}[\tilde{X}] \approx \frac{2\pi\sigma^2}{4n} \approx 1.57 \cdot \frac{\sigma^2}{n}$

Thus, for large n , the variance of \tilde{X} is more than 50 percent larger than the variance of \bar{X} .

- However, there are distributions for which the sample median has a smaller variance than the sample mean, as shown in the following example.

Digression: The t distribution $t(n)$

- The density of the $t(n)$ distribution with n degrees of freedom is:

$$f_t(x; n) = \frac{\Gamma(\frac{n+1}{2})}{\sqrt{n\pi} \Gamma(\frac{n}{2})} \left(1 + \frac{x^2}{n}\right)^{-(n+1)/2}$$

- The $t(1)$ distribution is also called the Cauchy or (in particle physics) Breit–Wigner distribution.
- The k -th moment μ_k exists only for $k < n$.
- For $n \rightarrow \infty$, the $t(n)$ distribution converges to the standard normal distribution.

Example

Let X_1, \dots, X_n be a sample from the t distribution $t(3)$. The variance of \bar{X} is equal to.

$$\text{var}(\bar{X}) = \frac{3}{n}$$

The variance of \tilde{X} for large n is equal to

$$\text{var}(\tilde{X}) = \frac{1}{4nf(0)^2} = \frac{1.8506}{n} \approx 0.62 \cdot \frac{3}{n}$$

Thus, it is almost 40 percent smaller than the variance of \bar{X} .

The Exponential Distribution $\text{Ex}(\tau)$

- The **exponential** or **waiting time distribution** is an important family of distributions in science and engineering. We denote it by $\text{Ex}(\tau)$.
- Its density is:

$$f_{\text{Ex}}(x; \tau) = \frac{1}{\tau} e^{-x/\tau}$$

- Its distribution function is:

$$F_{\text{Ex}}(x; \tau) = 1 - e^{-x/\tau}$$

- The exponential distribution is a special case of the **gamma distribution**: $\text{Ex}(\tau)$ is equal to $\text{Ga}(1, \tau)$.
- The mode M is at $x = 0$.

Mixture Models and the
EM Algorithm

- The α quantile of the exponential distribution $\text{Ex}(\tau)$ is:

$$\gamma_{\alpha;1,\tau} = -\tau \ln(1 - \alpha)$$

- Consequently, the median of the distribution is at $x = \tau \ln 2$.
- The exponential distribution is the distribution of a waiting time **without memory**: The distribution is independent of the time at which the timing starts.
- This behavior is typical for physical processes like the radioactive decay of an atom or the decay of an unstable elementary particle.

Mixture Models and the
EM Algorithm

- We observe a process in which certain events occur at random times.
- If the waiting times between events are independent and exponentially distributed with mean τ , we speak of a **Poisson process** with intensity $\lambda = 1/\tau$.
- The number X of events per time unit is then independent and **Poisson-distributed** according to $\text{Po}(\lambda)$.
- Conversely, if the number X of events per unit time is independent and Poisson-distributed according to $\text{Po}(\lambda)$, then the waiting times are exponentially distributed with mean $\tau = 1/\lambda$.
- In a Poisson process of intensity λ , the number of events per time interval of length T is again Poisson distributed according to $\text{Po}(\lambda T)$.
- The sum of two Poisson processes is again a Poisson process. Its intensity is the sum of the intensities of the summands.

The Poisson Process

Examples of Poisson processes

- The number of decays per unit time in a (large) radioactive source.
- The number of particles per unit time in cosmic radiation.
- The number of pixel errors on a LCD display.
- The number of rare events per time unit (insurance claims, suicides, accidents).

The Poisson distribution $Po(\lambda)$

- The density of the Poisson distribution is:

$$f_{Po}(k; \lambda) = \frac{\lambda^k}{k!} \cdot e^{-\lambda}, \quad k \in \mathbb{N}_0$$

- The mode M is equal to

$$M = \begin{cases} \lfloor \lambda \rfloor, & \text{if } \lambda \notin \mathbb{N} \\ \lambda \text{ and } \lambda - 1, & \text{if } \lambda \in \mathbb{N} \\ 0, & \text{if } \lambda = 0 \end{cases}$$

- The distribution function can be expressed by the distribution function of the gamma distribution $Ga(k+1, 1)$:

$$F_{Po}(k; \lambda) = 1 - F_{Ga}(\lambda; k+1, 1)$$

The Poisson distribution for large λ

- A random variable distributed according to $\text{Po}(\lambda)$ can be represented as a sum of λ $\text{Po}(1)$ -distributed random variables.
- Therefore, according to the central limit theorem, the Poisson distribution for $\lambda \rightarrow \infty$ must tend toward a normal distribution.
- The following figure shows the distribution function of the Poisson distribution $\text{Po}(\lambda)$ with $\lambda = 25$, and the distribution function of the normal distribution $\text{No}(\mu, \sigma^2)$ with $\mu = \lambda = 25$ and $\sigma^2 = \lambda = 25$.

Theorem

Let X_1, \dots, X_n be a sample from the Poisson distribution $\text{Po}(\lambda)$ and \bar{X} be the sample mean. Then:

- \bar{X} is an unbiased and consistent estimator of λ .
- \bar{X} is efficient.
- \bar{X} is asymptotically normally distributed with mean $\mu = \lambda$ and variance $\sigma^2 = \lambda/n$.

The alternative or Bernoulli distribution $A_1(p)$

- A Bernoulli experiment or alternative experiment has two possible outcomes, “success” and “failure” respectively.
- The random variable X assigns the value 1 to success and 0 to failure.
- If p is the probability of success, the density $f_{A_1}(x; p)$ is as follows:

$$f_{A_1}(0; p) = 1 - p, \quad f_{A_1}(1; p) = p$$

or

$$f_{A_1}(x; p) = p^x (1 - p)^{1-x}, \quad x \in \{0, 1\}$$

- If the alternative test is performed n times independently, there are 2^n possible outcomes, namely all sequences of the form $e = (i_1, \dots, i_n)$, $i_j \in \{0, 1\}$.
- The discrete random variable Y maps the sequence e to the frequency of 1:

$$Y(e) = \sum_{j=1}^n i_j$$

- The range of values of Y is the set $\{0, 1, \dots, n\}$. Mapped to the number k ($0 \leq k \leq n$) are all sequences where 1 occurs exactly k times. There are C_k^n such sequences, and each has probability $p^k(1-p)^{n-k}$.

The binomial distribution $\text{Bi}(n, p)$

- Therefore, the density f of Y is:

$$f_{\text{Bi}}(k; p, n) = \binom{n}{k} p^k (1-p)^{n-k}, \quad 0 \leq k \leq n$$

- The distribution of Y is called **binomial distribution** $\text{Bi}(n, p)$ with parameters n and p .
- The following holds:

$$\sum_{k=0}^n f_{\text{Bi}}(k; p, n) = \sum_{k=0}^n \binom{n}{k} p^k (1-p)^{n-k} = 1$$

This is just the binomial theorem.

Digression: The beta distribution $\text{Be}(a, b)$

- The density of the beta distribution is:

$$f_{\text{Be}}(x; a, b) = \frac{x^{a-1}(1-x)^{b-1}}{B(a, b)} \cdot I_{[0,1]}(x)$$

- Its distribution function is the regularized incomplete beta function:

$$F_{\text{Be}}(x; a, b) = \int_0^x \frac{t^{a-1}(1-t)^{b-1}}{B(a, b)} dt$$

- The mode M is at $x = (a-1)/(a+b-2)$ when $a, b > 1$.

The Binomial Distribution for Large n

- A random variable distributed according to $\text{Bi}(n, p)$ can be represented as a sum of n Bernoulli distributed random variables.
- Therefore, according to the central limit theorem, the binomial distribution for $n \rightarrow \infty$ and fixed p must tend toward a normal distribution.
- The following figure shows the distribution function of the binomial distribution $\text{Bi}(n, p)$ with $n = 200$ and $p = 0.1$, and the distribution function of the normal distribution $\text{No}(\mu, \sigma^2)$ with $\mu = np = 20$ and $\sigma^2 = np(1 - p) = 18$.

The binomial distribution for large n and $p = \lambda/n$

- In the limit $n \rightarrow \infty$ and $p = \lambda/n \rightarrow 0$ the binomial distribution $\text{Bi}(n, p)$ tends to the Poisson distribution $\text{Po}(\lambda)$:

$$\lim_{n \rightarrow \infty} \binom{n}{k} (\lambda/n)^k (1 - \lambda/n)^{n-k} = \frac{\lambda^k}{k!} \cdot e^{-\lambda}$$

- Thus, if the number of trials n is increased and the probability of success is decreased in inverse proportion, the number of successes is asymptotically Poisson distributed.

Drawing and Placing Back

- Given a population of N objects, of which M objects exhibit a certain **property** E .
- n objects are drawn, each object having the same probability of being drawn.
- Each object drawn is immediately put back.
- The number of objects drawn exhibiting feature E is a random variable X .
- X is then **binomially distributed** according to $\text{Bi}(n, M/N)$.
- If N and M are much larger than n , X is binomially distributed to a good approximation even if drawn objects are **not** put back.
- An example of this is a survey in which the sample size n is much smaller than N and M .

Pulling without Putting Back

- Population of N objects, of which M objects exhibit **feature** E .
- n objects are drawn, each object having the same probability of being drawn.
- Once drawn, objects are **not** put back.
- The number of objects with feature E is a random variable X .
- The distribution of X is called a **hypergeometric distribution** $\text{Hy}(N, M, n)$.

The moments of the hypergeometric distribution

Let $X \sim \text{Hy}(N, M, n)$ and $p = M/N$. Then:

- $E[X] = \frac{nM}{N} = np$

- $\text{var}[X] = \frac{nM}{N} \frac{N-M}{N} \frac{N-n}{N-1} = np(1-p) \frac{N-n}{N-1}$

- The term $(N-n)(N-1)$ in the variance is called **correction for finiteness**. It is close to 1 if $N \gg n$.
- If $N \gg n$ and $M \gg n$, the hypergeometric distribution can be approximated by the binomial distribution since in this case drawing from the sample does not significantly change the composition of the population.

Definition (ML Estimator)

- Let X_1, \dots, X_n be a sample with joint density $g(x_1, \dots, x_n | \vartheta)$. The function

$$L(\vartheta | X_1, \dots, X_n) = g(X_1, \dots, X_n | \vartheta)$$

is called the **likelihood function** of the sample.

- The **plausible** or **maximum likelihood estimator** $\hat{\vartheta}$ is that value of ϑ that maximizes the likelihood function of the sample.
- Often, instead of the likelihood function, we maximize its logarithm, the log-likelihood function $\ell(\vartheta) = \ln L(\vartheta)$.
- In simple cases we can maximize analytically. If this is not possible, we maximize numerically.

Maximum Likelihood Estimator

of Data Analysis

W. Waltenberger

Point Estimators

Normally Distributed
Data

Exponentially Distributed
Data

Poisson Distributed Data

Data from Bernoulli and
Drawing Experiments

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

- The ML estimator is invariant under (differentiable) transformations of the parameter: if $\hat{\vartheta}$ is the ML estimator of ϑ , then $h(\hat{\vartheta})$ is the ML estimator of $h(\vartheta)$.

Example (ML estimator of a Bernoulli parameter)

Let X_1, \dots, X_n be a sample from the Bernoulli distribution $\text{Al}(p)$.

The joint density is:

$$g(x_1, \dots, x_n | p) = \prod_{i=1}^n p^{x_i} (1-p)^{1-x_i} = p^{\sum x_i} (1-p)^{n-\sum x_i}$$

Therefore, the log-likelihood function is:

$$\ell(p) = \sum_{i=1}^n X_i \ln p + \left(n - \sum_{i=1}^n X_i \right) \ln(1-p)$$

Maximum Likelihood Estimator

W. Waltenberger

Point Estimators

Normally Distributed
Data

Exponentially Distributed
Data

Poisson Distributed Data

Data from Bernoulli and
Drawing Experiments

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

Example (Continuation)

Deriving w.r.t. p results in:

$$\frac{\partial \ell(p)}{\partial p} = \frac{1}{p} \sum_{i=1}^n X_i - \frac{1}{1-p} \left(n - \sum_{i=1}^n X_i \right)$$

Setting the derivative to zero and solving for p yields:

$$\hat{p} = \frac{1}{n} \sum_{i=1}^n X_i = \bar{X}$$

The ML estimator is unbiased and efficient.

Example (ML estimator of a Poisson parameter)

Let X_1, \dots, X_n be a sample from the Poisson distribution $\text{Po}(\lambda)$. The joint density is:

$$g(x_1, \dots, x_n | \lambda) = \prod_{i=1}^n \frac{\lambda^{x_i} e^{-\lambda}}{x_i!}$$

Therefore, the log-likelihood function is:

$$\ell(\lambda) = \sum_{i=1}^n [X_i \ln \lambda - \lambda - \ln(x_i!)]$$

Deriving to λ yields:

$$\frac{\partial \ell(\lambda)}{\partial \lambda} = \frac{1}{\lambda} \sum_{i=1}^n X_i - n$$

Maximum Likelihood Estimator

Example (Continuation)

Setting the derivative to zero and solving for λ yields:

$$\hat{\lambda} = \frac{1}{n} \sum_{i=1}^n X_i = \bar{X}$$

. The ML estimator is unbiased and efficient.

Mixture Models and the
EM Algorithm

Example (Continuation)

Zeroing the derivatives and solving for μ and σ^2 yields:

$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^n X_i = \bar{X}$$

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^2 = \frac{n-1}{n} S^2$$

The ML estimator of μ is unbiased and efficient. The ML estimator of σ^2 is asymptotically unbiased and asymptotically efficient.

The ML estimator of σ is equal to

$$\hat{\sigma} = \sqrt{\frac{n-1}{n}} S$$

It is also asymptotically unbiased and asymptotically efficient.

Mixture Models and the
EM Algorithm

- The normalized likelihood function can be interpreted as an a posteriori distribution of the estimated parameter.
- For large n , the variance of the likelihood estimate $\hat{\vartheta}$ can therefore be determined from the second central moment of the normalized likelihood function.
- If the estimated parameter ϑ is the mean of a normal distribution, then this procedure is exact for any n :

$$L(\vartheta) = \frac{1}{\sigma^n \sqrt{2\pi}^n} \exp \left[-\frac{n}{2\sigma^2} \left((\hat{\vartheta} - \vartheta)^2 + \frac{1}{n} \sum (x_i - \hat{\vartheta})^2 \right) \right]$$

- If $L(\vartheta)$ is normalized, it is the 'density' of a normal distribution with mean $\hat{\vartheta}$ and variance $\frac{\sigma^2}{n}$, i.e. the variance of the estimate $\hat{\vartheta} = \frac{1}{n} \sum x_i$.

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

Example (Estimation of the parameter a of a gamma distribution)

The sample $\mathbf{X} = (X_1, \dots, X_n)$ consists of $n = 200$ values drawn independently from a $\text{Ga}(a, 1)$ distribution:

$$f(x_i|a) = \frac{x_i^{a-1} e^{-x_i}}{\Gamma(a)}, \quad i = 1, \dots, n$$

The (unknown) true value of a is $a_t = 2$. The log-likelihood function is

$$\ln L(a|\mathbf{X}) = \sum_{i=1}^n \ln f(X_i|a) = (a-1) \sum_{i=1}^n \ln X_i - \sum_{i=1}^n X_i - n \ln \Gamma(a)$$

Maximum Likelihood Estimator

Example (Continuation)

Numerical maximization of $\ln L(a)$ results in the maximum likelihood estimate \hat{a} . The experiment is repeated N times and the estimates of each experiment $(\hat{a}^{(k)}, k = 1, \dots, N)$ are histogrammed. Comparison of the individual (normalized) likelihood function with the histogram ($N = 500$) shows good agreement between the standard deviations.

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

Example (Continuation)

With known b , the Fisher information of the sample with respect to a is equal to

$$I_a = n \frac{d^2 \ln \Gamma(a)}{da^2} \approx 128.99$$

This corresponds to a standard deviation $\sigma = 0.088$. Thus, the ML estimator is practically efficient.

Because of $E[\bar{X}] = a$, \bar{X} is an unbiased estimator of a for all n . However, it has a larger standard deviation than the ML estimator:

$$\sigma[\bar{X}] = \sqrt{\frac{a}{n}} = 0.1$$

On the other hand, it is much easier to calculate.

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

- The ML estimator has the following important property:

Theorem

If the first two derivatives of $L(\vartheta)$ exist, the information $I_g(\vartheta)$ exists for all ϑ , and if $E[(\ln L)'] = 0$, then the maximum likelihood estimate $\hat{\vartheta}$ is asymptotically normally distributed with mean ϑ and variance $1/I_g(\vartheta)$. $\hat{\vartheta}$ is therefore asymptotically unbiased and asymptotically efficient.

- From this, the following follows immediately:

Theorem

The likelihood estimator $\hat{\vartheta}$ is consistent (under the same assumptions).

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

Example (ML estimation of the location parameter of a Cauchy distribution)

Let $\mathbf{X} = (X_1, \dots, X_n)$ be a sample from the Cauchy distribution $t(1)$ with location parameter μ . The joint density is:

$$g(x_1, \dots, x_n | \mu) = \prod_{i=1}^n \frac{1}{\pi [1 + (x_i - \mu)^2]}$$

Therefore, the log-likelihood function is:

$$\ell(\mu | \mathbf{X}) = -n \ln \pi - \sum_{i=1}^n \ln [1 + (X_i - \mu)^2]$$

The maximum $\hat{\mu}$ of $\ell(\mu | \mathbf{X})$ must be found numerically.

Maximum Likelihood Estimator

Example (Continuation)

It can be shown that the Fisher information of the sample is equal to

$$I_{\mu} = \frac{n}{2}$$

Therefore, for large samples, the variance of the ML estimator $\hat{\mu}$ must be approximately equal to $2/n$.

The sample median \tilde{X} is also a consistent estimator for μ . Its variance is asymptotically equal to $\pi^2/(4n) \approx 2.47/n$. Thus, it is about 23 percent larger than the variance of the ML estimator.

The sample mean \overline{X} , on the other hand, is **no** consistent estimator for μ . Indeed, one can show that \overline{X} has the same distribution as a single observation.

Data

Exponentially Distributed
Data

Poisson Distributed Data

Data from Bernoulli and
Drawing Experiments

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

Example (ML estimation of the upper limit of a uniform distribution)

Let X_1, \dots, X_n be a sample from the uniform distribution $\text{Un}(0, b)$ with upper limit b . The joint density is:

$$g(x_1, \dots, x_n | b) = \frac{1}{b^n}, 0 \leq x_1, \dots, x_n \leq b$$

Therefore, the largest value of the likelihood function is at:

$$\hat{b} = \max_i X_i$$

Since the maximum sits at the boundary of the variable's domain, the usual asymptotic properties do not apply.

Maximum Likelihood Estimator

W. Waltenberger

Point Estimators

Normally Distributed
Data

Exponentially Distributed
Data

Poisson Distributed Data

Data from Bernoulli and
Drawing Experiments

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

Example (Continuation)

The density of $\hat{b} = \max_i X_i$ is:

$$f(x) = \frac{nx^{n-1}}{b^n}$$

From this, expectation and variance can be calculated:

$$E[\hat{b}] = \frac{bn}{n+1}, \quad \text{var}[\hat{b}] = \frac{b^2n}{(n+2)(n+1)^2}$$

The estimator is asymptotically unbiased, but the variance approaches zero, as does $1/n^2$! The estimator is also not asymptotically normally distributed.

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

- If the likelihood function is (approximately) normal, the log-likelihood function is (approximately) parabolic.
- In this case, error intervals of the ML estimator can be read from the log-likelihood function.

Width of the log-likelihood function

Let $\ell(\vartheta)$ be the log-likelihood function of the parameter ϑ , further $\hat{\vartheta}$ be the ML estimator and $\sigma[\hat{\vartheta}]$ its standard deviation. Then, approximately:

$$\ell(\hat{\vartheta} - k\sigma[\hat{\vartheta}]) = \ell(\hat{\vartheta} + k\sigma[\hat{\vartheta}]) = \ell(\hat{\vartheta}) - k^2/2$$

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

- If two parameters $\boldsymbol{\vartheta} = (\vartheta_1, \vartheta_2)$ are estimated simultaneously, the log-likelihood function $\ell(\boldsymbol{\vartheta})$ is asymptotically an elliptic paraboloid.
- The contour lines of $\ell(\boldsymbol{\vartheta})$ are then ellipses.
- If a contour line is to have the probability content $1 - \alpha$, then its height z is equal to

$$z = \ell(\hat{\boldsymbol{\vartheta}}) - \frac{1}{2} \chi_{1-\alpha;2}^2 = \ell(\hat{\boldsymbol{\vartheta}}) + \ln(\alpha)$$

- For example, the ellipse with $1 - \alpha = 0.95$ is the contour line to the height $z = \ell(\hat{\boldsymbol{\vartheta}}) - 2.996$.
- The covariance matrix of the ML estimator $\hat{\boldsymbol{\vartheta}}$ can be approximated by the inverse negative Hessian matrix at the maximum.

Example

Mean μ and standard deviation σ of a normal distribution are estimated from a sample of size $n = 500$. The true values are $\mu = 5, \sigma = 1.5$, the estimated values are $\hat{\mu} = 4.980, \hat{\sigma} = 1.529$. The inverse negative Hessian matrix in the maximum of log-likelihood function is equal to.

$$\mathbf{V} = \begin{pmatrix} 0.0047 & 0 \\ 0 & 0.0023 \end{pmatrix}$$

This corresponds to a standard error of $\sigma[\hat{\mu}] = 0.0684$ and $\sigma[\hat{\sigma}] = 0.0483$. The inverse Fisher information matrix is equal to

$$\mathbf{I}_{\mu, \sigma} = \begin{pmatrix} 0.0045 & 0 \\ 0 & 0.0022 \end{pmatrix}$$

EM Algorithm

Example (Continuation)

Contour lines of log-likelihood function with probability contents 0.3935, 0.9, 0.95, 0.99.

Maximum Likelihood Estimator

Numerical Calculation of the Hessian matrix

- Let $\ell(\vartheta_1, \vartheta_2)$ be the log-likelihood function, with maximum in $(\hat{\vartheta}_1, \hat{\vartheta}_2)$.
- Furthermore let $\varepsilon_1, \varepsilon_2 > 0$ and

$$\mathbf{L} = \begin{pmatrix} \ell(\hat{\vartheta}_1 - \varepsilon_1, \hat{\vartheta}_2 - \varepsilon_2) & \ell(\hat{\vartheta}_1, \hat{\vartheta}_2 - \varepsilon_2) & \ell(\hat{\vartheta}_1 + \varepsilon_1, \hat{\vartheta}_2 - \varepsilon_2) \\ \ell(\hat{\vartheta}_1 - \varepsilon_1, \hat{\vartheta}_2) & \ell(\hat{\vartheta}_1, \hat{\vartheta}_2) & \ell(\hat{\vartheta}_1 + \varepsilon_1, \hat{\vartheta}_2) \\ \ell(\hat{\vartheta}_1 - \varepsilon_1, \hat{\vartheta}_2 + \varepsilon_2) & \ell(\hat{\vartheta}_1, \hat{\vartheta}_2 + \varepsilon_2) & \ell(\hat{\vartheta}_1 + \varepsilon_1, \hat{\vartheta}_2 + \varepsilon_2) \end{pmatrix}$$

- The Hessian matrix is then equal to

$$\mathbf{H} = \begin{pmatrix} \frac{\mathbf{L}_{21} + \mathbf{L}_{23} - 2\mathbf{L}_{22}}{\varepsilon_1^2} & \frac{\mathbf{L}_{11} + \mathbf{L}_{33} - \mathbf{L}_{13} - \mathbf{L}_{31}}{4\varepsilon_1\varepsilon_2} \\ \frac{\mathbf{L}_{11} + \mathbf{L}_{33} - \mathbf{L}_{13} - \mathbf{L}_{31}}{4\varepsilon_1\varepsilon_2} & \frac{\mathbf{L}_{12} + \mathbf{L}_{32} - 2\mathbf{L}_{22}}{\varepsilon_2^2} \end{pmatrix}$$

Mixture Models and the
EM Algorithm

- Experimental observations often come from different distributions, e.g. signal and background.
- Such data can be described by a **mixture model**.

Definition (Mixture Model)

A **mixture model** with k components is a distribution whose density has the following form:

$$f(x) = \sum_{j=1}^k w_j f_j(x), \quad w_j \geq 0, \quad \sum_{j=1}^k w_j = 1$$

The w_j are nonnegative and are called the **weights** of the components.

- The components f_j are typically normal distributions or other simple distributions.

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

- The estimation of the parameters can be performed with the maximum likelihood method.
- In the case of a mixture of normal distributions, the log-likelihood function of a sample \mathbf{X} of size n is:

$$\ell(\boldsymbol{\vartheta}) = \sum_{i=1}^n \ln \left(\sum_{j=1}^k w_j \cdot \varphi(x_i; \mu_j, \sigma_j^2) \right)$$

- The log-likelihood function must be maximized numerically, subject to the constraint $\sum_{j=1}^k w_j = 1$.
- The log-likelihood function may have several local maxima. In this case, repeated maximization with different initial values is recommended.

Maximum Likelihood
Estimator

Mixture Models and the
EM Algorithm

- One method for maximizing the log-likelihood function is the **EM algorithm**.
- The EM algorithm is iterative. The choice of initial values can influence which local maximum is reached.
- In each iteration, Bayes' theorem is used to calculate the a posteriori probabilities p_{ij} that observation i comes from component j .
- The means and variances of the components are then estimated by weighted sample means and weighted sample variances, respectively.
- These two steps are iterated until the estimate stabilizes.
- The log-likelihood function cannot get smaller in any iteration; however, reaching the global maximum is **not** guaranteed.

Mixture Models and the
EM Algorithm

EM algorithm for a mixture of normal distributions

- 1 Choice of initial values for mixture parameters
 $\vartheta = (\mu_1, \dots, \mu_k, \sigma_1^2, \dots, \sigma_k^2, w_1, \dots, w_k)$
- 2 Calculation of p_{ij} and p_j for observation X_i , component φ_j :

$$p_{ij} = \frac{w_j \varphi(X_i; \mu_j, \sigma_j^2)}{\sum_{l=1}^k w_l \varphi(X_i; \mu_l, \sigma_l^2)}, \quad p_j = \sum_{i=1}^n p_{ij}$$

- 3 Estimation of weights and moments:

$$w_j = \frac{p_j}{n}, \quad \mu_j = \frac{\sum_{i=1}^n p_{ij} X_i}{p_j}, \quad \sigma_j^2 = \frac{\sum_{i=1}^n p_{ij} (X_i - \mu_j)^2}{p_j}$$

- 4 Repeat steps 2 and 3 until convergence.

- Apart from the estimated value itself, its distribution around the true value is also of interest.
- We want to determine an interval from a sample that contains the true value with a certain probability.

Definition (Confidence Interval)

Let $\mathbf{X} = (X_1, \dots, X_n)$ be a sample from the distribution F with unknown parameter ϑ and $0 < \alpha < 1$. An interval with boundaries $G_1 = g_1(\mathbf{X})$ and $G_2 = g_2(\mathbf{X})$ is called a **confidence interval** with a certainty $1 - \alpha$ if:

$$\begin{aligned}P(G_1 \leq G_2) &= 1 \\P(G_1 \leq \vartheta \leq G_2) &\geq 1 - \alpha\end{aligned}$$

Such an interval is called a $(1 - \alpha)$ confidence interval. α is called the **significance level**.

- For each value of certainty $1 - \alpha$ there are many different confidence intervals.
- If F is continuous, there are infinitely many confidence intervals with certainty $1 - \alpha$.
- If F is discrete, the confidence is usually greater than $1 - \alpha$.
- The confidence interval is called **symmetric** if:

$$P(\vartheta \leq G_1) = P(\vartheta \geq G_2)$$

- The confidence interval is called **one-sided** if:

$$\text{lower tail: } P(\vartheta \leq G_2) \geq 1 - \alpha \quad \text{or}$$

$$\text{upper tail: } P(G_1 \leq \vartheta) \geq 1 - \alpha$$

Example

Let \mathbf{X} be a sample of $\text{No}(\mu, \sigma^2)$ with unknown variance σ^2 . Then $(n-1)S^2/\sigma^2$ is χ^2 -distributed with $n-1$ degrees of freedom.

Therefore:

$$P\left(\frac{\sigma^2 \chi_{\alpha/2; n-1}^2}{n-1} \leq S^2 \leq \frac{\sigma^2 \chi_{1-\alpha/2; n-1}^2}{n-1}\right) = 1 - \alpha$$

The expression in the parenthesis can be transformed to:

$$\frac{(n-1)S^2}{\chi_{1-\alpha/2; n-1}^2} \leq \sigma^2 \leq \frac{(n-1)S^2}{\chi_{\alpha/2; n-1}^2}$$

From this follows

$$G_1(\mathbf{X}) = \frac{(n-1)S^2}{\chi_{1-\alpha/2; n-1}^2}, \quad G_2(\mathbf{X}) = \frac{(n-1)S^2}{\chi_{\alpha/2; n-1}^2}$$

- Let \mathbf{X} be a sample from the normal distribution $\text{No}(\mu, \sigma^2)$.
- \bar{X} is normally distributed according to $\text{No}(\mu, \sigma^2/n)$.
- If σ^2 is known, the standard score is

$$Z = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}}$$

standard normally distributed. From

$$P(-z_{1-\alpha/2} \leq Z \leq z_{1-\alpha/2}) = 1 - \alpha$$

then follows

$$P(\bar{X} - z_{1-\alpha/2}\sigma/\sqrt{n} \leq \mu \leq \bar{X} + z_{1-\alpha/2}\sigma/\sqrt{n}) = 1 - \alpha$$

- If σ^2 is unknown, σ^2 is estimated by the sample variance S^2 .
The standard score

$$T = \frac{\bar{X} - \mu}{S/\sqrt{n}}$$

is then t-distributed with $n - 1$ degrees of freedom. From

$$P(-t_{1-\alpha/2;n-1} \leq T \leq t_{1-\alpha/2;n-1}) = 1 - \alpha$$

follows

Symmetric CI for the Mean, Unknown Variance

$$G_1(\mathbf{x}) = \bar{X} - t_{1-\alpha/2;n-1}S/\sqrt{n}, \quad G_2(\mathbf{X}) = \bar{X} + t_{1-\alpha/2;n-1}S/\sqrt{n}$$

Example

A sample of size $n = 50$ from the standard normal distribution has sample mean $\bar{X} = 0.0540$ and sample variance $S^2 = 1.0987$. If the variance is assumed to be known, the symmetric 95%-confidence interval for μ is:

$$G_1 = 0.0540 - 1.96/\sqrt{50} = -0.2232$$

$$G_2 = 0.0540 + 1.96/\sqrt{50} = 0.3312$$

If the variance is assumed to be unknown, the symmetric 95%-confidence interval for μ is:

$$G_1 = 0.0540 - 2.01 \cdot 1.0482/\sqrt{50} = -0.2439$$

$$G_2 = 0.0540 + 2.01 \cdot 1.0482/\sqrt{50} = 0.3519$$

Lower Tail CI for the Variance

$$G_1(\mathbf{X}) = 0, \quad G_2(\mathbf{X}) = \frac{(n-1)S^2}{\chi_{\alpha;n-1}^2}$$

Upper Tail CI for the Variance

$$G_1(\mathbf{X}) = \frac{(n-1)S^2}{\chi_{1-\alpha;n-1}^2}, \quad G_2(\mathbf{X}) = \infty$$

Example

A sample of size $n = 50$ from the normal distribution $\text{No}(0, 4)$ has sample variance $S^2 = 4.3949$. The symmetric 95%-confidence interval for σ^2 is:

$$G_1 = 49 \cdot 4.3949 / 70.2224 = 3.0667$$

$$G_2 = 49 \cdot 4.3949 / 31.5549 = 6.8246$$

If the quantiles of the χ^2 distribution $\chi^2(n-1)$ are replaced by the quantiles of the normal distribution $\text{No}(n-1, 2(n-1))$, the confidence intervals:

$$G_1 = 49 \cdot 4.3949 / 68.4027 = 3.1483$$

$$G_2 = 49 \cdot 4.3949 / 29.5973 = 7.2760$$

Exponentially Distributed
Data

Poisson Distributed Data

Binomially Distributed
Data

Data from Other
Distributions

Example

Angabe: In a survey of $n = 400$ people, $k = 157$ people claim to know product X . We are looking for a 95% confidence interval for the degree of familiarity p .

Clopper-Pearson:

$$G_1(k) = \beta_{0.025;157,244} = 0.3443$$

$$G_2(k) = \beta_{0.975;158,243} = 0.4423$$

Approximation by normal distribution:

$\hat{p} = 0.3925$, $z_{0.975} = 1.96$. Using the bootstrap procedure, $\sigma[\hat{p}] = 0.0244$ is obtained. The limits of the confidence interval are therefore

$$G_1 = 0.3925 - 1.96 \cdot 0.0244 = 0.3446$$

$$G_2 = 0.3925 + 1.96 \cdot 0.0244 = 0.4404$$

Binomially Distributed Data

of Data Analysis

W. Waltenberger

Basic Terminology

General Construction
According to Neyman

Normally Distributed
Data

Exponentially Distributed
Data

Poisson Distributed Data

Binomially Distributed
Data

Data from Other
Distributions

Example (Continuation)

Using the robust procedure, we get $\sigma[\hat{p}] = 0.025$ and the bounds

$$G_1 = 0.3925 - 1.96 \cdot 0.025 = 0.3435$$

$$G_2 = 0.3925 + 1.96 \cdot 0.025 = 0.4415$$

The robust interval is only marginally larger than the bootstrap interval.

With the Agresti-Coull correction, we get $\hat{p} = 0.3936$. The limits of the confidence interval are then

$$G_1 = 0.3936 - 1.96 \cdot 0.0244 = 0.3457$$

$$G_2 = 0.3936 + 1.96 \cdot 0.0244 = 0.4414$$

- Let $\mathbf{X} = (X_1, \dots, X_n)$ be a sample from distribution F with mean μ and variance σ^2 .
- Given the central limit theorem, the standard score Z of the sample mean

$$Z = \frac{\bar{X} - \mu}{S/\sqrt{n}}$$

converges against a normal distribution for large samples. Thus, **approximately**

$$P(\bar{X} - z_{1-\alpha/2}S/\sqrt{n} \leq \mu \leq \bar{X} + z_{1-\alpha/2}S/\sqrt{n}) \approx 1 - \alpha$$

Approximate CI for the Mean

$$G_1(\mathbf{X}) = \bar{X} - z_{1-\alpha/2}S/\sqrt{n}, \quad G_2(\mathbf{X}) = \bar{X} + z_{1-\alpha/2}S/\sqrt{n}$$

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

- We observe a sample X_1, \dots, X_n from a distribution F .
- A test is to determine whether the observations are compatible with some assumption about F .
- The assumption is called the **null hypothesis** H_0 .
- If the form of F is specified except for one or more parameters, the test is called **parametric**.
- If the form of F is not specified, the test is called **nonparametric** or **parameter free**.
- The test decides whether the sample is consistent with the hypothesis, not whether the hypothesis is correct!
- If the sample is consistent with the hypothesis, the hypothesis may still deviate from the truth, albeit only to a limited extent.

General Procedure

- A test statistic T is calculated from the sample.
- The range of values of T is divided, depending on H_0 , into a **rejection region** (critical region) C and an **acceptance region** C' .
- The acceptance region is usually a **prediction interval** for T .
- If the value of T falls within the rejection range, H_0 is discarded.
- Otherwise, H_0 is retained for the time being.
- However, this is not a confirmation of H_0 . It simply means that the data are consistent with the hypothesis.

One-sided and Two-sided Tests

- If the acceptance region is the symmetric prediction interval for T , the test is called **two-sided**. The critical region then breaks down into two disjoint intervals.
- If the acceptance region is an interval of the form $T \leq c$ or $T \geq c$, the test is called **one-sided**. The critical region is then an interval of the form $T > c$ or $T < c$.

Tests and Confidence Intervals

- In many cases, the acceptance region is a confidence interval for the tested parameter.
- The null hypothesis is rejected if the hypothesized value is outside the confidence interval, as it is considered to be insufficiently plausible.

The p -value

- A test can alternatively be formulated using the p -value $P(T)$.
- The p -value indicates how likely it is to observe the value T or an even more extreme value, given the null hypothesis.
- Two-sided test: If $F_0(x)$ is the distribution function of T under the null hypothesis, then the p -value is equal to

$$P(T) = 2 \min(F_0(T), 1 - F_0(T))$$

- One-sided test: if $F_0(x)$ is the distribution function of T under the null hypothesis, then the p -value is equal to

$$P(T) = F_0(T) \text{ or } p = 1 - F_0(T)$$

- The null hypothesis is rejected if $P(T) < \alpha$.

Significance and Power

- In any hypothesis test, we distinguish between two types of errors.
 - **Type I error:** The hypothesis H_0 is rejected although it is true.
 - **Type II error:** The hypothesis H_0 is retained, although it is not true.
- The distribution of T under H_0 is determined.
- The rejection region is determined such that the probability of a type I error is at most equal to a value of α .
- α is called the **significance level**, or the **test size**. Common values are $\alpha = 0.05, 0.01, 0.005$.

Introduction

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

- Once the rejection region is defined, the probability of a type II error of an „alternative hypothesis“ H_1 , $\beta(H_1)$ can be calculated.
- $1 - \beta(H_1)$ is called the **power** of the test for H_1 .
- The power should never be smaller than α .
- The test is called **unbiased**, if the power is never less than α .
- A goal of test theory is to construct unbiased tests with maximum power (uniformly most powerful unbiased test, UMPU).

Likelihood-Ratio Tests

Non-Parametric Tests

- We consider a sample X_1, \dots, X_n from a distribution F specified up to one or more parameters.
- Hypothesis tests about F are called **parametric**.
- A null hypothesis H_0 can be thought of as a subset of the parameter space Θ .
- The test decides whether the sample is consistent with the hypothesis.
- Before testing, ascertain that the assumed parametric form is reasonable.

- First, the test statistic T and the significance level α are chosen.
- The critical region C is then defined such that

$$P(T \in C | \vartheta \in H_0) \leq \alpha$$

- An **alternative hypothesis** H_1 to the null hypothesis H_0 can be formulated.
- H_1 can also be constructed as a subset of the parameter space Θ .
- If the significance level α is fixed, the power of the test can be computed for each $\vartheta \in H_1$:

$$1 - \beta(\vartheta) = P(T \in C | \vartheta \in H_1)$$

- $1 - \beta(\vartheta)$ is called the **power function** of the test.

Example with Exponential Distribution

- X_1, \dots, X_n is an exponentially distributed sample of $\text{Ex}(\tau)$.
- The hypothesis $H_0 : \tau = \tau_0$ is to be tested given the sample.
- As test statistic T we choose the sample mean: $T = \bar{X}$.
- Under H_0 , T has the following density:

$$f(t) = \frac{t^{n-1}}{(\tau_0/n)^n \Gamma(n)} \exp\left(-\frac{t}{\tau_0/n}\right)$$

- T is thus distributed according to $\text{Ga}(n, \tau_0/n)$.
- The symmetric prediction interval $[y_1(\tau_0), y_2(\tau_0)]$ for T at confidence $1 - \alpha$ is given by:

$$y_1(\tau_0) = \gamma_{\alpha/2; n, \tau_0/n}, \quad y_2(\tau_0) = \gamma_{1-\alpha/2; n, \tau_0/n}$$

- Therefore, the rejection region at significance α is the set

$$C = [0, y_1(\tau_0)] \cup [y_2(\tau_0), \infty[$$

- So H_0 is rejected if T is too “far away” from the hypothetical value τ_0 .
- The power of the test for any given value of τ is given by:

$$1 - \beta(\tau) = P(T \in C) = G(y_1(\tau)) + 1 - G(y_2(\tau))$$

where G is the distribution function of the $\text{Ga}(n, \tau/n)$ -distribution.

- The test is biased because, e.g. for $\tau_0 = 1$ and $n = 25$.

$$1 - \beta(0.986) = 0.0495 < \alpha$$

Expected Value with Known Variance

- X_1, \dots, X_n is a normally distributed sample of $\text{No}(\mu, \sigma^2)$ with known σ^2 .
- The hypothesis $H_0 : \mu = \mu_0$ is to be tested against the alternative hypothesis $H_1 : \mu \neq \mu_0$.
- As the test statistic T we choose the standard score of the sample mean:

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{\sigma}$$

- Under H_0 , $T \sim \text{No}(0, 1)$.
- H_0 is rejected if T is not within the prediction interval at significance α of the standard normal distribution.

Non-Parametric Tests

Two-sided Test

- The hypothesis H_0 is rejected if

$$|T| = \frac{\sqrt{n} |\bar{X} - \mu_0|}{\sigma} > z_{1-\alpha/2}$$

- The power function for a value μ is given by:

$$1 - \beta(\mu) = P(T \in C) = G(z_{\alpha/2}) + 1 - G(z_{(1-\alpha)/2})$$

where G is the distribution function of
 $\text{No}(\sqrt{n}(\mu - \mu_0)/\sigma, 1)$ -distribution.

- The test is unbiased.

Non-Parametric Tests

One-sided Test

- The hypothesis $H_0 : \mu \leq \mu_0$ is to be tested with the test statistic T against the alternative hypothesis $H_1 : \mu > \mu_0$.
- H_0 is rejected if T is “too large”.
- A rejection region with significance level α is

$$C = [z_{1-\alpha}, \infty[$$

- Thus, the hypothesis H_0 is rejected if

$$T = \frac{\sqrt{n} (\bar{X} - \mu_0)}{\sigma} > z_{1-\alpha}$$

Expected Value with Unknown Variance: t-Test

- X_1, \dots, X_n is a normally distributed sample of $\text{No}(\mu, \sigma^2)$ with unknown σ^2 .
- The hypothesis $H_0 : \mu = \mu_0$ is to be tested against the alternative hypothesis $H_1 : \mu \neq \mu_0$.
- As test statistic T we choose the standard score of the sample mean, using the sample variance S^2 :

$$T = \frac{\sqrt{n}(\bar{X} - \mu_0)}{S}$$

- Under H_0 , $T \sim t(n-1)$.

Tests for Normally Distributed Data

Likelihood-Ratio Tests

Non-Parametric Tests

- H_0 is rejected if T does not fall within the prediction interval at significance α of the t-distribution with $n - 1$ degrees of freedom.
- The rejection region with significance level α is given as

$$C =] - \infty, t_{\alpha/2; n-1}] \cup [t_{1-\alpha/2; n-1}, \infty[$$

where $t_{p; n}$ is the quantile of the t-distribution with $n - 1$ degrees of freedom at level p .

- Thus, the hypothesis H_0 is rejected if

$$|T| = \frac{\sqrt{n} |\bar{X} - \mu_0|}{S} > t_{1-\alpha/2; n-1}$$

Equality of Two Expected Values

- X_1, \dots, X_n and Y_1, \dots, Y_m are two independent normally distributed samples of $\text{No}(\mu_x, \sigma_x^2)$ and $\text{No}(\mu_y, \sigma_y^2)$.
- The hypothesis $H_0 : \mu_x = \mu_y$ is supposed to be tested against the alternative hypothesis $H_1 : \mu_x \neq \mu_y$ to be tested.
- If the **variances are known**, we choose as test statistic T the difference of the sample means:

$$T = \bar{X} - \bar{Y}$$

- Assuming H_0 , $T \sim \text{No}(0, \sigma_x^2/n + \sigma_y^2/m)$.

Non-Parametric Tests

- If the **variances are unknown and equal**, the variance can be estimated from the combined ('pooled') sample:

$$S^2 = \frac{(n-1)S_x^2 + (m-1)S_y^2}{n+m-2}$$

- Under H_0 ,

$$T = \frac{\bar{X} - \bar{Y}}{\sqrt{S^2(1/n + 1/m)}}$$

t-distributed with $n + m - 2$ degrees of freedom.

- Thus, the hypothesis H_0 is rejected if

$$|T| > t_{1-\alpha/2; n+m-2}$$

where $t_{1-\alpha/2; n+m-2}$ is the quantile of the t-distribution with $n + m - 2$ degrees of freedom.

t-Test for Paired Samples

- Paired samples $(X_1, Y_1), \dots, (X_n, Y_n)$ occur when the same quantity is measured twice for each observed object, before and after a given intervention.
- The effect of the intervention is described by the differences $W_i = Y_i - X_i, i = 1, \dots, n$.
- We assume that W_1, \dots, W_n is normally distributed with mean μ_w and unknown variance σ_w^2 .
- The hypothesis $H_0 : \mu_w = 0$ (no effect of the intervention) is to be tested against the alternative hypothesis $H_1 : \mu_w \neq 0$.
- This is performed via the t-test for individual samples.

Tests for Normally Distributed Data

Test of Variance

- X_1, \dots, X_n is a normally distributed sample with unknown expected value μ and unknown variance σ^2 .
- The hypothesis $H_0 : \sigma^2 = \sigma_0^2$ is to be tested against the alternative hypothesis $H_1 : \sigma^2 \neq \sigma_0^2$.
- As test statistic T we choose:

$$T = \frac{(n-1)S^2}{\sigma_0^2}$$

- Assuming H_0 , T is χ^2 -distributed with $n-1$ degrees of freedom.

Non-Parametric Tests

- Thus, the hypothesis H_0 is rejected if

$$T < \chi_{\alpha/2;n-1}^2 \quad \text{or} \quad T > \chi_{1-\alpha/2;n-1}^2$$

where $\chi_{p;k}^2$ is the p -quantile of the χ^2 -distribution with k degrees of freedom.

- The power function for a value σ^2 is given by:

$$1 - \beta(\sigma^2) = G(\sigma_0^2/\sigma^2 \cdot \chi_{\alpha/2;n-1}^2) + 1 - G(\sigma_0^2/\sigma^2 \cdot \chi_{1-\alpha/2;n-1}^2)$$

where G is the distribution function of the $\chi^2(n-1)$ -distribution.

- The test is not unbiased.

Test for Two-sided Expected Value

- Let X_1, \dots, X_n be a Poisson distributed sample $\text{Po}(\lambda)$.
- The hypothesis $H_0 : \lambda = \lambda_0$ is to be tested against the alternative hypothesis $H_1 : \lambda \neq \lambda_0$.
- As test statistic T we choose the sample sum:

$$T = \sum_{i=1}^n X_i$$

- T is Poisson distributed according to $\text{Po}(n\lambda)$.
- H_0 is rejected if T is “too small” or “too large”, i.e. if

$$\sum_{k=0}^T \frac{(n\lambda_0)^k e^{-n\lambda_0}}{k!} < \alpha/2 \text{ or } \sum_{k=T}^{\infty} \frac{(n\lambda_0)^k e^{-n\lambda_0}}{k!} < \alpha/2$$

Example

A manufacturer aims to produce no more than 25 defective components per day on average in a factory. A sample of 5 days results in 28,34,32,38 and 22 defective components. Has the manufacturer achieved his goal?

The test statistic $T = 154$. Therefore,

$$P(T) = \sum_{k=T}^{\infty} \frac{(125)^k e^{-125}}{k!} = 0.0067 < 0.01$$

$$\gamma_{0.01;154,1} = 126.61 < 154$$

Thus, the hypothesis can be refuted at a significance level of 1 percent.

Approximation by Normal Distribution

- If n is sufficiently large, the distribution of T can be approximated by a normal distribution $N_0(n\lambda, n\lambda)$.
- H_0 is rejected if the standard score

$$Z = \frac{T - n\lambda_0}{\sqrt{n\lambda_0}}$$

is not within a prediction interval of level $1 - \alpha$ of the standard normal distribution.

Example

Given the last example, the approximation yields:

$$Z = 2.5938 > z_{0.99} = 2.3263$$

Thus, the hypothesis can be rejected at a significance level of 1 percent.

or

$$\sum_{i=k}^n \binom{n}{i} p_0^i (1 - p_0)^{n-i} = F_{\text{Be}}(1 - p_0; n - k, k + 1) < \alpha/2$$

holds where $F_{\text{Be}}(x; a, b)$ is the distribution function of $\text{Be}(a, b)$.

Tests for Binomially Distributed Data

One-sided Test for Parameter p

- The hypothesis $H_0 : p \leq p_0$ is to be tested on the basis of the observation k against the alternative hypothesis $H_1 : p > p_0$.
- H_0 is rejected if k is “too large” and thus the p -value is too small:

$$P(k) = \sum_{i=k}^n \binom{n}{i} p_0^i (1 - p_0)^{n-i} = B(p_0; k, n - k + 1) < \alpha$$

- The hypothesis $H_0 : p \geq p_0$ is rejected if k is “too small” and thus the p -value is too small:

$$P(k) = \sum_{i=0}^k \binom{n}{i} p_0^i (1 - p_0)^{n-i} = B(1 - p_0; n - k, k + 1) < \alpha$$

Likelihood-Ratio Tests

Non-Parametric Tests

Example

A manufacturer claims that no more than 2 percent of a certain component are defective. In a sample of size 300, 9 pieces are defective. Can the manufacturer's claim be refuted?

$$P(k) = \sum_{i=9}^{300} \binom{300}{i} 0.02^i 0.98^{300-i} = 0.1507$$

The manufacturer's claim cannot be refuted at a 5 percent significance level.

Tests for Binomially Distributed Data

Approximation by Normal Distribution

- If n is sufficiently large, the distribution of k can be approximated by a normal distribution $\text{No}(np, np(1 - p))$.
- H_0 is rejected if the standard score is

$$Z = \frac{k - np_0}{\sqrt{np(1 - p_0)}}$$

does not lie within a prediction interval of level $1 - \alpha$ of the standard normal distribution.

- Two-sided test: H_0 is rejected if

$$Z < z_{\alpha/2} \text{ or } Z > z_{1-\alpha/2}$$

- One-sided test: H_0 is rejected if

$$Z < z_{\alpha} \text{ or } Z > z_{1-\alpha}$$

Likelihood-Ratio Tests

Non-Parametric Tests

- A hypothesis is called **simple** if it has no free parameters, i.e. if the statistical model is completely defined.
- Given two **simple** hypotheses $H_0 : \theta = \theta_0$, and $H_1 : \theta = \theta_1$, and data \mathbf{X} , a test can be constructed from the ratio of the likelihoods.

$$\Lambda(\mathbf{X}) := \frac{L(\theta_0|\mathbf{X})}{L(\theta_1|\mathbf{X})}$$

- The null hypothesis H_0 is rejected if the test statistic is below a certain value, $\Lambda(\mathbf{X}) \leq \eta$.
- Here η is chosen such that $\alpha = P(\Lambda(\mathbf{X}) \leq \eta | H_0)$. As usual, the significance level („test size”) α is again freely chosen. Common values are $\alpha = 0.05, 0.1$ or 0.01 .

Likelihood-Ratio Tests

Non-Parametric Tests

Example (Likelihood-Ratio Test)

Let $\mathbf{X} = (X_1, \dots, X_n)$ be a sample from a normal distribution $N(\mu, \sigma^2)$ with fixed μ . We test for the *variance* of the distribution, with $H_0 : \sigma^2 = \sigma_0^2$ and $H_1 : \sigma^2 = \sigma_1^2, \sigma_1^2 > \sigma_0^2$.

- The likelihood ratio is

$$\Lambda(\mathbf{X}) = \frac{L(\sigma_0^2 | \mathbf{X})}{L(\sigma_1^2 | \mathbf{X})} = \left(\frac{\sigma_0^2}{\sigma_1^2} \right)^{-\frac{n}{2}} \exp \left\{ -\frac{\sigma_0^{-2} - \sigma_1^{-2}}{2} \sum_{i=1}^n (X_i - \mu)^2 \right\}$$

- $\sum_{i=1}^n (X_i - \mu)^2$ is the only term of the likelihood ratio that depends on the data, therefore H_0 is rejected if the sum is extreme enough under the null hypothesis. Since we required that $\sigma_1^2 > \sigma_0^2$, we can restrict ourselves to test whether the sum is too large (one-sided test).

Likelihood-Ratio Tests

Non-Parametric Tests

Neyman-Pearson lemma

The likelihood-ratio test is the test with asymptotically maximum power, for a given significance level α .

- A hypothesis that is not *simple* is called **composite**.
- Often the alternative hypothesis H_1 is constructed as the complement of the null hypothesis, i.e.
 $H_0 : \theta \in \Theta_0, H_1 : \theta \in \Theta_0^C$.
- The alternative hypothesis $H_1 : \theta \in \Theta$ can also be formulated to *contain* the null hypothesis $H_0 : \theta \in \Theta_0$, with $\Theta_0 \in \Theta$. In this case we speak of a **nested model**. The Neyman-Pearson lemma holds for the likelihood-ratio test:

$$\Lambda(\mathbf{X}) = \frac{\sup\{L(\theta|\mathbf{X}) : \theta \in \Theta_0\}}{\sup\{L(\theta|\mathbf{X}) : \theta \in \Theta\}}$$

Wilks' Theorem

For nested models, under H_0 the test statistic $T = -2 \ln \Lambda(\mathbf{X})$ converges asymptotically towards a $\chi^2(n)$ -distribution with n degrees of freedom, where n is given as the difference of the dimensionalities of Θ and Θ_0 : $n = \dim(\Theta) - \dim(\Theta_0)$.

- Wilks' theorem can be used to specify η : $\eta = \chi^2_{1-\alpha;n}$, where α is again the significance level and n is the number of degrees of freedom of the test.

Likelihood-Ratio Tests

Non-Parametric Tests

Example (Likelihood Ratio Test for P_λ)

We construct a test for the intensity parameter λ of a Poisson distribution, $H_0 : \lambda = \lambda_0, H_1 : \lambda \neq \lambda_0$. Let $\mathbf{X} = (X_1, \dots, X_n)$ be a sample of the distribution.

- The supremum of the alternative hypothesis H_1 (the „Maximum Likelihood“) is at $\lambda = \bar{X}$.
- From this follows for the likelihood ratio $\Lambda(\mathbf{X})$:

$$\Lambda(\mathbf{X}) = e^{n(\bar{X} - \lambda_0)} \prod_{i=1}^n \left(\frac{\lambda_0}{\bar{X}} \right)^{X_i}$$

- The test statistic $T = -2 \ln \Lambda(\mathbf{X})$:

$$T = -2n \left[\bar{X} - \lambda_0 + \bar{X} \ln \left(\frac{\lambda_0}{\bar{X}} \right) \right]$$

Likelihood-Ratio Tests

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Basics

Tests for Normally Distributed
Data

Tests for Poisson Distributed
Data

Tests for Binomially
Distributed Data

Likelihood-Ratio Tests

Non-Parametric Tests

Example (Likelihood Ratio Test for P_λ , continued)

- The test statistic $T = -2 \ln \Lambda(X)$:

$$T = 2n \left[\lambda_0 - \bar{X} + \bar{X} \ln \left(\frac{\bar{X}}{\lambda_0} \right) \right]$$

- According to Wilks' theorem T is asymptotically χ^2 -distributed with one degree of freedom. The 95% quantile of χ_1^2 is 3.84. The critical region of the test at a significance level of 5% is therefore

$$C = [3.84, \infty)$$

The Chi-squared Test

The Kolmogorov-Smirnov Test

The Chi-squared Test for Discrete Data

- The sample X_1, \dots, X_n comes from a discrete distribution with range of values $\{1, \dots, k\}$.
- We test the hypothesis H_0 that the density f has values $f(j) = p_j, j = 1, \dots, k$:

$$H_0 : P(X_i = j) = p_j, j = 1, \dots, k$$

vs.

$$H_1 : P(X_i = j) \neq p_j, \text{ for at least one } j$$

- Let Y_j be the number of observations equal to j .
- Under the null hypothesis, Y_1, \dots, Y_k is multinomially distributed according to $\text{Mu}(n, p_1, \dots, p_k)$ and $E[Y_j] = np_j$.

The Chi-squared Test

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

Excursion: the Multinomial Distribution $\text{Mu}(n, p_1, \dots, p_d)$

- The Bernoulli experiment can be generalized to allow not only two, but d elementary events e_1, \dots, e_d , to which are assigned the probabilities p_1, \dots, p_d , which only must satisfy

$$\sum_{i=1}^d p_i = 1$$

- Performing the **generalized alternative experiment** n times, the elementary events are the sequences of the form:

$$(e_{i_1}, \dots, e_{i_n}), \quad 1 \leq i_j \leq d$$

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

- If the n observations are independent, then:

$$P(e_{i_1}, \dots, e_{i_n}) = \prod_{j=1}^n P(e_{i_j}) = \prod_{j=1}^n p_{i_j} = \prod_{i=1}^d p_i^{n_i}$$

Where n_i is the number of occurrences of e_i . Therefore, the sum of n_i is n .

- The d -dimensional random variable $\mathbf{X} = (X_1, \dots, X_d)$ maps the sequence $(e_{i_1}, \dots, e_{i_n})$ to the vector (n_1, \dots, n_d) . In this way $n!/(n_1! \cdots n_d!)$ sequences are mapped onto the same vector.
- Therefore, the density of \mathbf{X} is:

$$f_{\mathbf{X}}(n_1, \dots, n_d) = \frac{n!}{n_1! \cdots n_d!} \prod_{i=1}^d p_i^{n_i}, \quad \sum_{i=1}^d n_i = n, \quad \sum_{i=1}^d p_i = 1$$

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

- The distribution of \mathbf{X} is called **multinomial distribution** with parameters n and p_1, \dots, p_d : $P_{\mathbf{X}} = \text{Mu}(n, p_1, \dots, p_d)$
- The classic example of a multinomially distributed random vector is the histogram (grouped frequency distribution), which is used to graphically represent the (absolute) **experimental frequencies**.
- X_i is the number of times the random variable R , its experimental outcome, falls into group i .
- Let the probability that R falls into group i be equal to p_i .
- If n outcomes are filled into the histogram, the group contents (X_1, \dots, X_d) are multinomially distributed according to $\text{Mu}(n, p_1, \dots, p_d)$.

The Chi-squared Test

The Kolmogorov-Smirnov Test

• A histogram

The Chi-squared Test

The moments of the $\text{Mu}(n, p_1, \dots, p_d)$ -distribution

Let $\mathbf{X} = (X_1, \dots, X_d) \sim \text{Mu}(n, p_1, \dots, p_d)$. Then:

- $E[X_i] = np_i$
- $\text{var}[X_i] = np_i(1 - p_i)$
- $\text{cov}[X_i, X_j] = -np_i p_j$

Definition (covariance)

The **covariance** of two random variables X and Y is defined by:

$$\text{cov}[X, Y] = E[XY] - E[X]E[Y]$$

If $\text{cov}[X, Y] = 0$, X and Y are called **uncorrelated**.

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

Properties of Covariance

- $\text{cov}[aX + b, cY + d] = ac \cdot \text{cov}[X, Y]$
- $\text{var}[X + Y] = \text{var}[X] + \text{var}[Y] + 2\text{cov}[X, Y]$
- $\text{cov}[X, X] = \text{var}[X]$

Definition (correlation)

The **correlation coefficient** $\rho[X, Y]$ is defined by:

$$\rho[X, Y] = \frac{\text{cov}[X, Y]}{\sqrt{\text{var}[X]\text{var}[Y]}}$$

The Chi-squared Test

- $\rho[aX + b, cY + d] = \rho[X, Y]$
- $\rho[X, X] = 1$

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

Definition (covariance matrix)

Let $\mathbf{X} = (X_1, \dots, X_d)$ be a random vector. If all variances and covariances exist, they are combined in the **covariance matrix** $\mathbf{C} = \text{Cov}[\mathbf{X}]$:

$$\mathbf{C}_{ij} = \text{cov}[X_i, X_j]$$

Similarly, the correlations are summarized in the **correlation matrix** $\mathbf{R} = \text{Cor}[X, Y]$:

$$\mathbf{R}_{ij} = \rho[X_i, X_j]$$

- The covariance matrix is always **symmetric** and **positive definite**. All eigenvalues are real and positive.
- The correlation matrix is also **symmetric** and **positive definite**. All diagonal elements are equal to 1.

The Chi-squared Test

- The test statistic compares the observed frequencies Y_j with their expected values:

$$T = \sum_{j=1}^k \frac{(Y_j - np_j)^2}{np_j}$$

- The null hypothesis is rejected if T is large.
- The critical region can be determined according to the following result.

Theorem

Assuming the null hypothesis, the random variable T is asymptotically – i.e. for $n \rightarrow \infty$ – χ^2 -distributed with $k - 1$ degrees of freedom.

The Chi-squared Test

- If the test is to have significance level α , H_0 is rejected if

$$T \geq \chi_{1-\alpha; k-1}^2$$

where $\chi_{1-\alpha; k-1}^2$ is the $(1 - \alpha)$ quantile of the χ^2 -distribution with $k - 1$ degrees of freedom.

- The reason that T has only $k - 1$ degrees of freedom is the linear relationship between the Y_j :

$$\sum_{j=1}^k Y_j = n$$

- As a rule of thumb, n should be large enough that $np_j > 5, j = 1, \dots, k$.
- If this is not satisfied, the rejection range should be determined by simulation.

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

Example

We use a sample of size 50 to test whether a die is symmetric, that is, whether the number of eyes X has the following distribution:

$$P(X = 1) = \dots = P(X = 6) = \frac{1}{6}$$

A simulation of $N = 100000$ samples yields:

$$\bar{T} = 5.000, \quad S_T^2 = 9.789$$

The 0.95 quantile of the χ^2 -distribution with five degrees of freedom is $\chi_{0.95;5}^2 = 11.07$, and

$$P(T \geq 11.07) = 0.048$$

The Chi-squared Test

of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

The Chi-squared Test for Continuous Data

- Let the sample X_1, \dots, X_n come from a continuous distribution F .
- We test the hypothesis $H_0 : F(x) = F_0(x)$.
- To this end, we divide the range of values of X into k groups G_1, \dots, G_k .
- Let Y_j be the number of observations in group G_j .
- Under the null hypothesis, Y_1, \dots, Y_k is multinomially distributed according to $\text{Mu}(n, p_1, \dots, p_k)$ and $E[Y_j] = np_j$, with.

$$p_j = P(X \in G_j | H_0)$$

- The test continues as in the discrete case.

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

Unknown Parameters

- The null hypothesis need not be fully specified. We consider the case where the p_j still depend on unknown parameters ϑ :

$$P(X \in G_j) = p_j(\vartheta)$$

- The statistic T is now a function of the unknown parameters:

$$T(\vartheta) = \sum_{j=1}^k \frac{(Y_j - np_j(\vartheta))^2}{np_j(\vartheta)}$$

- First, the parameters are estimated, by ML estimation or minimization of T :

$$\tilde{\vartheta} = \arg \min_{\vartheta} T(\vartheta)$$

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

- The critical area can be determined according to the following result.

Theorem

If m parameters are estimated from the sample, $T(\tilde{\theta})$ is asymptotically χ^2 -distributed with $k - 1 - m$ degrees of freedom.

- If the test is to have significance level α , H_0 is rejected if

$$T \geq \chi^2_{1-\alpha; k-1-m}$$

where $\chi^2_{1-\alpha; k-1-m}$ is the $(1 - \alpha)$ quantile of the χ^2 -distribution with $k - 1 - m$ degrees of freedom.

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

Example

Angabe: The number of occupational accidents was surveyed in a large company over a period of 30 weeks. The following values resulted:

$$\mathbf{X} = \{8, 0, 0, 1, 3, 4, 0, 2, 12, 5, 1, 8, 0, 2, 0, \\ 1, 9, 3, 4, 5, 3, 3, 4, 7, 4, 0, 1, 2, 1, 2\}$$

To test the hypothesis that the observations are Poisson distributed according to $\text{Po}(\lambda)$.

Lösung: The observations are divided into five groups:

group	1	2	3	4	5
X	0	1	2-3	4-5	> 5

The frequencies of the groups are:

$$Y_1 = 6, Y_2 = 5, Y_3 = 8, Y_4 = 6, Y_5 = 5$$

The Chi-squared Test

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Parametric Tests

Non-Parametric Tests

The Chi-squared Test

The Kolmogorov-Smirnov Test

Example (Continuation)

The estimated value for λ is the sample mean:

$$\tilde{\lambda} = 3.1667$$

The expected values of Y_j assuming $H_0 = \text{Po}(\tilde{\lambda})$ are:

j	1	2	3	4	5
$E[Y_1]$	1.2643	4.0037	13.0304	8.6522	3.0493

The test size T is equal to $T = 21.99$. The 99% quantile of the χ^2 -distribution with three degrees of freedom is equal to $\chi^2_{0.99;3} = 11.35$. Thus, the hypothesis that the observations are Poisson distributed must be rejected.

Definition (Multidimensional Random Variable)

A mapping \mathbf{X} :

$$\omega \in \Omega \mapsto \mathbf{x} = \mathbf{X}(\omega) \in \mathbb{R}^d$$

that assigns a real vector $\mathbf{x} \in \mathbb{R}^d$ to each element ω of the sample space Ω is called a d -dimensional random variable.

- Each component of a d -dimensional random variable is itself a random variable.
- Each component can be discrete or continuous.

Data Reconciliation

Example

The bivariate (two-dimensional) random variable $\mathbf{X} = (X_1, X_2)$ assigns the numbers of eyes (i, j) to the outcome (e_i, e_j) of the roll with two dice. If all outcomes are equally probable, $P_{\mathbf{X}}$ is given by:

$$P_{\mathbf{X}}(\{(i, j)\}) = \frac{1}{36}$$

The density $f_{\mathbf{X}}$ is:

$$f_{\mathbf{X}}(x_1, x_2) = \begin{cases} \frac{1}{36}, & x_1 \in \{1, \dots, 6\} \cap x_2 \in \{1, \dots, 6\} \\ 0, & \text{other} \end{cases}$$

Data Reconciliation

Example (Continuation)

Therefore, the distribution function $F_{\mathbf{X}}$ is:

$$F_{\mathbf{X}}(x_1, x_2) = P(X_1 \leq x_1 \cap X_2 \leq x_2) = \sum_{i \leq x_1 \cap j \leq x_2} f(i, j)$$

For example, $F_{\mathbf{X}}(3, 4) = \sum_{i \leq 3 \cap j \leq 4} \frac{1}{36} = \frac{12}{36} = \frac{1}{3}$.

- Given the countability of the elementary events, they can also be uniquely mapped onto \mathbb{R} by a univariate random variable Y , e.g.:

$$Y : (e_i, e_j) \longrightarrow 6i + j - 6$$

The set of values of Y are the natural numbers between 1 and 36, and P_Y is given by:

$$P_Y(\{k\}) = \frac{1}{36}, \quad 1 \leq k \leq 36$$

Data Reconciliation

- If X_1 and X_2 are two (discrete or continuous) univariate random variables, then $\mathbf{X} = (X_1, X_2)$ is a bivariate random variable. The distribution (distribution function, density) of \mathbf{X} is also called the **joint distribution** of X_1 and X_2 .
- The following problem now arises: can we calculate the distribution of X_1 or X_2 from the joint distribution?

Marginal Distributions and Conditional Distributions

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Multidimensional
Random Variable

Basic Terminology

Marginal Distributions and
Conditional Distributions

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

- Let F be the distribution function and f be the density of continuous random variables $\mathbf{X} = (X_1, X_2)$. Then the distribution function F_1 of X_1 is given by:

$$\begin{aligned} F_1(x_1) &= P(X_1 \leq x_1) = P(X_1 \leq x_1 \cap -\infty < X_2 < \infty) = \\ &= \int_{-\infty}^{x_1} \int_{-\infty}^{\infty} f(x_1, x_2) dx_2 dx_1 \end{aligned}$$

- It follows that

$$f_1(x_1) = \int_{-\infty}^{\infty} f(x_1, x_2) dx_2$$

is the density of X_1 .

Simple Regression

Multiple Regression

Data Reconciliation

Definition (marginal distribution)

Let $\mathbf{X} = (X_1, X_2)$ be a bivariate continuous random variable with distribution function F and density f . The distribution of X_1 is called the **marginal distribution** of X_1 with respect to \mathbf{X} . Its density f_1 is:

$$f_1(x_1) = \int_{-\infty}^{\infty} f(x_1, x_2) dx_2.$$

Analogously, if $\mathbf{X} = (X_1, X_2)$ is discrete with density f , then the density f_1 of the marginal distribution of X_1 with respect to \mathbf{X} is given by:

$$f_1(k_1) = \sum_{k_2} f(k_1, k_2)$$

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

- So the distributions of X_1 and X_2 can be calculated from the joint distribution of X_1 and X_2 .
- The reverse process is generally not possible because the joint distribution also contains information about correlations (coupling) between X_1 and X_2 .
- Let X_1 and X_2 be two discrete random variables with joint density $f(k_1, k_2)$ and marginal densities $f_1(k_1)$ and $f_2(k_2)$. Then the conditional probability of the event $X_1 = k_1$ under the condition $X_2 = k_2$ is given by:

$$P(X_1 = k_1 | X_2 = k_2) = \frac{P(X_1 = k_1 \cap X_2 = k_2)}{P(X_2 = k_2)} = \frac{f(k_1, k_2)}{f_2(k_2)}$$

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

Definition (Conditional Density)

Let $\mathbf{X} = (X_1, X_2)$ be a bivariate discrete random variable with density $f(k_1, k_2)$ and marginal distribution densities $f_1(k_1)$ and $f_2(k_2)$, respectively. The function $f(k_1|k_2)$, defined by:

$$f(k_1|k_2) = \frac{f(k_1, k_2)}{f_2(k_2)}$$

is called the conditional density of X_1 **given** X_2 .

- For fixed k_2 , the conditional density is the density of a distribution, the **conditional distribution** of X_1 given $X_2 = k_2$.

Marginal Distributions and Conditional Distributions

Statistical Methods

W. Waltenberger

Introduction

Multidimensional
Random Variable

Basic Terminology

Marginal Distributions and
Conditional Distributions

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

- If $\mathbf{X} = (X_1, X_2)$ is continuous, then analogously $f(x_1|x_2)$ is defined by:

$$f(x_1|x_2) = \frac{f(x_1, x_2)}{f_2(x_2)} \quad (f_2(x_2) \neq 0)$$

- $f(x_1|x_2)$ is for fixed x_2 the density of a distribution, the distribution of X_1 conditioned by $X_2 = x_2$.
- It can easily be verified that $f(x_1|x_2)$ is indeed a density:

$$\int_{-\infty}^{\infty} f(x_1|x_2) dx_1 = \int_{-\infty}^{\infty} \frac{f(x_1, x_2)}{f_2(x_2)} dx_1 = \frac{f_2(x_2)}{f_2(x_2)} = 1$$

and analogously for discrete \mathbf{X} .

Conditional Density Properties

$$f(x_1, x_2) = f(x_1|x_2) \cdot f_2(x_2)$$

$$f_1(x_1) = \int_{-\infty}^{\infty} f(x_1|x_2) \cdot f_2(x_2) dx_2$$

and analogously for discrete densities.

Definition (independence of random variables)

If the (unconditional) density of the marginal distribution of X_1 is equal to the density conditioned by X_2 , then X_1 and X_2 are called **independent**.

$$X_1 \text{ and } X_2 \text{ independent} \iff f(x_1|x_2) = f_1(x_1).$$

Marginal Distributions and Conditional Distributions

- For independent random variables X_1 and X_2 :

$$\begin{aligned}f(x_1|x_2) = f_1(x_1) &\iff f(x_2|x_1) = f_2(x_2) \\ &\iff f(x_1, x_2) = f_1(x_1) \cdot f_2(x_2)\end{aligned}$$

and analogously for discrete \mathbf{X} .

Properties of Independent Random Variables

- $f(x_1, x_2) = f_1(x_1) \cdot f_2(x_2)$
 - $E[X_1 X_2] = E[X_1] \cdot E[X_2]$
 - $\text{cov}[X_1, X_2] = \rho[X_1, X_2] = 0$
- Uncorrelated random variables are not necessarily also independent!

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

- If $\mathbf{X} = (X_1, \dots, X_d)$, $d > 2$, then the definitions of the marginal distribution, conditional densities and independence must be generalized accordingly.
- The density f_{i_1, \dots, i_m} of the marginal distribution of X_{i_1}, \dots, X_{i_m} is obtained by integrating or summing over all other variables.
- The density of X_i given X_j is given by:

$$f(x_i|x_j) = \frac{f_{i,j}(x_i, x_j)}{f_j(x_j)}$$

where $f_{i,j}(x_i, x_j)$ is the marginal distribution density of X_i, X_j .

- X_{i_1}, \dots, X_{i_k} are called independent if the densities of their marginal distributions are the product of the densities of the marginal distributions of each X_{i_j} .

Simple Regression

Multiple Regression

Data Reconciliation

Example (The Acceptance or Detection Probability)

Let X be a random variable with density $f(x)$. If X takes the value x , then there is a probability $a(x)$ that x is actually observed. One now defines a random variable I that is 1 if x is observed and 0 otherwise. Then I is Bernoulli distributed under the condition $X = x$ according to $\text{Al}(a(x))$:

$$P(I = 1|X = x) = a(x)$$

$$P(I = 0|X = x) = 1 - a(x)$$

Therefore, the joint density of X and I is:

$$f(x, 1) = a(x)f(x)$$

$$f(x, 0) = [1 - a(x)]f(x)$$

Marginal Distributions and Conditional Distributions

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Multidimensional
Random Variable

Basic Terminology

Marginal Distributions and
Conditional Distributions

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

Example (Continuation)

Because experimentalists can only work with observed quantities, they restrict their sample to the detected events, i.e. they need the density of X under the condition that X is observed:

$$f_A(x) = f(x|I = 1) = \frac{f(x, 1)}{f_2(1)} = \frac{a(x)f(x)}{\int a(x)f(x) dx}$$

As a concrete example, consider the measurement of a lifetime. Let the measurement start at t_{\min} and end at t_{\max} . Then $a(t)$ has the following shape:

$$a(t) = \begin{cases} 0, & \text{for } t \leq t_{\min} \\ 1, & \text{for } t_{\min} < t \leq t_{\max} \\ 0, & \text{for } t > t_{\max} \end{cases}$$

Marginal Distributions and Conditional Distributions

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Multidimensional
Random Variable

Basic Terminology

Marginal Distributions and
Conditional Distributions

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

Example (Continuation)

For the measured probability density:

$$f_A(t) = \begin{cases} 0, & t \leq t_{\min} \\ \frac{\frac{1}{\tau} \exp(-t/\tau)}{\exp(-t_{\min}/\tau) - \exp(-t_{\max}/\tau)}, & t_{\min} \leq t < t_{\max} \\ 0, & t > t_{\max} \end{cases}$$

The denominator $[\exp(-t_{\min}/\tau) - \exp(-t_{\max}/\tau)]$ corrects for those particles that decay before t_{\min} or after t_{\max} .

The detection probability $a(t)$ can also have a much more complicated dependence on t . For example, whether or not a decay can be observed at t may depend on the nature and geometric configuration of the decay products.

Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

The multivariate normal distribution $\text{No}(\mu, \mathbf{V})$

- Its density is:

$$f(\mathbf{x}) = \frac{1}{(2\pi)^{\frac{d}{2}} \sqrt{|\mathbf{V}|}} \exp\left(-\frac{1}{2}(\mathbf{x} - \mu)^T \mathbf{V}^{-1}(\mathbf{x} - \mu)\right)$$

Moments

Let $\mathbf{X} = (X_1, \dots, X_d) \sim \text{No}(\mu, \mathbf{V})$. Then holds:

- $\mathbb{E}[\mathbf{X}] = \mu$
- $\text{Cov}[\mathbf{X}] = \mathbf{V}$
- \mathbf{V}^{-1} is also symmetric and positive definite, and is called a weight or information matrix.

The Multivariate Normal Distribution

Marginal Distributions and
Conditional Distributions

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

- If $\mathbf{X} \sim \text{No}(\boldsymbol{\mu}, \mathbf{V})$, then \mathbf{V} can be put to diagonal form as a positive definite symmetric matrix using an orthogonal transformation (rotation):

$$\mathbf{U}\mathbf{V}\mathbf{U}^T = \mathbf{D}^2$$

- All diagonal elements of \mathbf{D}^2 are positive. The random variable $\mathbf{Z} = \mathbf{D}\mathbf{U}(\mathbf{X} - \boldsymbol{\mu})$ is then distributed according to a multivariate standard normal distribution, i.e.:

$$\mathbf{E}[\mathbf{Z}] = \mathbf{0}, \quad \text{Cov}[\mathbf{Z}] = \mathbf{I}$$

The rotation \mathbf{U} is called a **principle axis transformation**.

The Multivariate Normal Distribution

Statistical Methods

W. Waltenberger

Introduction

Multidimensional
Random Variable

Basic Terminology

Marginal Distributions and
Conditional Distributions

The Multivariate Normal
Distribution

Multivariate Error Propagation

Simple Regression

Multiple Regression

Data Reconciliation

The bivariate normal distribution

- For $d = 2$ and $\mu = \mathbf{0}$, the density can be written as follows:

$$f(x, y) = \frac{1}{2\pi\sigma_x\sigma_y\sqrt{1-\rho^2}} \exp \left[-\frac{1}{2(1-\rho^2)} \left(\frac{x^2}{\sigma_x^2} - \frac{2\rho xy}{\sigma_x\sigma_y} + \frac{y^2}{\sigma_y^2} \right) \right]$$

- $\rho = \sigma_{xy}/(\sigma_x\sigma_y)$ is the correlation coefficient. If X and Y are uncorrelated, i.e. $\rho = 0$, it follows:

$$f(x, y) = \frac{1}{2\pi\sigma_x\sigma_y} \exp \left[-\frac{1}{2} \left(\frac{x^2}{\sigma_x^2} + \frac{y^2}{\sigma_y^2} \right) \right] = f_1(x) \cdot f_2(y)$$

- Two uncorrelated normally distributed random variables with a joint normal distribution are therefore **independent**.

- The simplest regression model is a straight line:

$$Y = \alpha + \beta x + \varepsilon, \quad \mathbb{E}[\varepsilon] = 0, \quad \text{var}[\varepsilon] = \sigma^2$$

- Let Y_1, \dots, Y_n be the results for the values x_1, \dots, x_n of the predictor variable x .
- α and β can be estimated using the principle of least squares error.
- The following objective function is minimized:

$$SS = \sum_{i=1}^n (Y_i - \alpha - \beta x_i)^2$$

- gradient of SS :

$$\frac{\partial SS}{\partial \alpha} = -2 \sum_{i=1}^n (Y_i - \alpha - \beta x_i), \quad \frac{\partial SS}{\partial \beta} = -2 \sum_{i=1}^n x_i (Y_i - \alpha - \beta x_i)$$

Data Reconciliation

- Zeroing the gradient results in the **normal equations**:

$$\sum_{i=1}^n Y_i = n\alpha + \beta \sum_{i=1}^n x_i$$

$$\sum_{i=1}^n x_i Y_i = \alpha \sum_{i=1}^n x_i + \beta \sum_{i=1}^n x_i^2$$

- The estimated regression coefficients are:

$$\hat{\beta} = \frac{\sum_{i=1}^n x_i Y_i - \bar{x} \sum_{i=1}^n Y_i}{\sum_{i=1}^n x_i^2 - n\bar{x}^2}$$
$$\hat{\alpha} = \bar{Y} - \hat{\beta}\bar{x}$$

Data Reconciliation

- The variability of the values Y_i is due to various reasons:
- On the one hand, there are systematic differences due to different values of x .
- On top of that there is the random scattering of the data.

Explained variability $SS^* = \sum_{i=1}^n (\hat{Y}_i - \bar{Y})^2 = r_{xy}^2 n s_Y^2$

Residual variability $SS_R = \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 = (1 - r_{xy}^2) n s_Y^2$

Total variability $SS_T = \sum_{i=1}^n (Y_i - \bar{Y})^2 = n s_Y^2$

Decomposition of Variability

$$SS_T = SS^* + SS_R$$

- The goodness of the regression line can be determined by the **coefficient of determination**:

Coefficient of determination of the regression

$$B = \frac{SS^*}{SS_T} = r_{xy}^2$$

- It indicates what proportion of the total variability can be explained by the correlation of x and Y .

- If $\beta = 0$, the result does not depend on the influence variables at all.
- A test of the null hypothesis $H_0 : \beta = 0$ against $H_1 : \beta \neq 0$ is based on the following theorem.

Theorem

If ε is normally distributed, then:

$$\frac{\hat{\alpha} - \alpha}{\hat{\sigma}_{\hat{\alpha}}}, \quad \frac{\hat{\beta} - \beta}{\hat{\sigma}_{\hat{\beta}}}$$

is t-distributed with $n - 2$ degrees of freedom, where

$$\hat{\sigma}_{\hat{\alpha}}^2 = \frac{\hat{\sigma}^2 \sum x_i^2}{n (\sum x_i^2 - n \bar{x}^2)}, \quad \hat{\sigma}_{\hat{\beta}}^2 = \frac{\hat{\sigma}^2}{\sum x_i^2 - n \bar{x}^2}$$

Data Reconciliation

- The null hypothesis $H_0 : \beta = 0$ is rejected, if the test statistic

$$T = \frac{\hat{\beta}}{\hat{\sigma}_{\hat{\beta}}}$$

is relatively small or relatively large, i.e. if

$$\frac{|\hat{\beta}|}{\hat{\sigma}_{\hat{\beta}}} > t_{1-\alpha/2; n-2}$$

where $t_{p; n-2}$ is the p -quantile of the t -distribution with $n - 2$ degrees of freedom.

- An analogous test can be performed for the null hypothesis $H_0 : \alpha = 0$.

Tests, Confidence and Prediction Intervals

Symmetric Confidence Intervals

$$\hat{\alpha} \pm \hat{\sigma}_{\hat{\alpha}} \cdot t_{1-\alpha/2; n-2}, \quad \hat{\beta} \pm \hat{\sigma}_{\hat{\beta}} \cdot t_{1-\alpha/2; n-2}$$

- For $n \gtrsim 50$, the quantiles of the t-distribution can be replaced by quantiles of the standard normal distribution.
- We want to predict the outcome $Y_0 = Y(x_0)$ for a given value x_0 of the influence variable x .
- The expected value of Y_0 is

$$E[Y_0] = \hat{\alpha} + \hat{\beta}x_0$$

- The variance of $E[Y_0]$ is obtained by error propagation:

$$\text{var}[E[Y_0]] = \sigma^2 \left[\frac{1}{n} + \frac{(\bar{x} - x_0)^2}{\sum x_i^2 - n\bar{x}^2} \right]$$

Nonlinear Regression

Data Reconciliation

- In practice, the dependence of the results on the regression coefficients is often nonlinear:

$$\mathbf{Y} = \mathbf{h}(\boldsymbol{\beta}) + \boldsymbol{\varepsilon}, \quad \text{Cov}[\boldsymbol{\varepsilon}] = \mathbf{V}$$

- If \mathbf{V} is known, the objective function is:

$$SS = [\mathbf{Y} - \mathbf{h}(\boldsymbol{\beta})]^T \mathbf{G} [\mathbf{Y} - \mathbf{h}(\boldsymbol{\beta})], \quad \mathbf{G} = \mathbf{V}^{-1}$$

- SS can be minimized using the Gauss-Newton method.
- For this \mathbf{h} is linearized at a point $\boldsymbol{\beta}_0$:

$$\mathbf{h}(\boldsymbol{\beta}) \approx \mathbf{h}(\boldsymbol{\beta}_0) + \mathbf{H}(\boldsymbol{\beta} - \boldsymbol{\beta}_0) = \mathbf{c} + \mathbf{H}\boldsymbol{\beta}, \quad \mathbf{H} = \left. \frac{\partial \mathbf{h}}{\partial \boldsymbol{\beta}} \right|_{\boldsymbol{\beta}_0}$$

Linear Constraints

Let $\mathbf{Y} = (Y_1, \dots, Y_n)^T$ be a vector of observations of the n unknown quantities $\boldsymbol{\beta} = (\beta_1, \dots, \beta_n)$:

$$\mathbf{Y} = \boldsymbol{\beta} + \boldsymbol{\epsilon}, \text{Cov}[\boldsymbol{\epsilon}] = \mathbf{V},$$

with known \mathbf{V} . Moreover, assume that the quantities $\boldsymbol{\beta}$ must satisfy the following independent linear constraints with r unknown parameters $\boldsymbol{\vartheta} = (\vartheta_1, \dots, \vartheta_r)^T$:

$$\mathbf{A}\boldsymbol{\beta} + \mathbf{B}\boldsymbol{\vartheta} = \mathbf{c}$$

Where \mathbf{A} is a matrix of dimension $m \times n$, \mathbf{B} is a matrix of dimension $m \times r$, and \mathbf{c} a $m \times 1$ dimensional column vector.

Example (Continuation)

β and ϑ are estimated according to the principle of least sum of squares of error. The objective function is

$$S(\beta) = (Y - \beta)^T G (Y - \beta), G = V^{-1}$$

under the condition:

$$A\beta + B\vartheta = c.$$

The problem is determined if $r \leq m$ and consistent if $m \leq n + r$. The minimization of S can be done using m Lagrangians $\lambda = (\lambda_1, \dots, \lambda_m)^T$. The extended objective function is

$$L(\beta, \vartheta, \lambda) = (Y - \beta)^T G (Y - \beta) + 2\lambda^T (A\beta + B\vartheta - c)$$

with gradients

$$\frac{\partial L}{\partial \beta} = -2G(Y - \beta) + 2A^T \lambda, \quad \frac{\partial L}{\partial \vartheta} = 2B^T \lambda, \quad \frac{\partial L}{\partial \lambda} = 2(A\beta + B\vartheta - c)$$

Example (Continuation)

Zeroing the gradient leads to the following system of linear equations:

$$\mathbf{G}\boldsymbol{\beta} + \mathbf{A}^T\boldsymbol{\lambda} = \mathbf{G}\mathbf{Y}$$

$$\mathbf{B}^T\boldsymbol{\lambda} = \mathbf{0}$$

$$\mathbf{A}\boldsymbol{\beta} + \mathbf{B}\boldsymbol{\vartheta} = \mathbf{c}$$

With the additional assumption $m \leq n$ and the labels $\mathbf{G}_A = .(\mathbf{A}\mathbf{V}\mathbf{A}^T)^{-1}$, $\mathbf{V}_B = (\mathbf{B}^T\mathbf{G}_A\mathbf{B})^{-1}$ we obtain the following closed-form solution:

$$\hat{\boldsymbol{\beta}} = \mathbf{Y} + \mathbf{V}\mathbf{A}^T\mathbf{G}_A[\mathbf{I} - \mathbf{B}\mathbf{V}_B^T\mathbf{G}_A](\mathbf{c} - \mathbf{A}\mathbf{Y})$$

$$\hat{\boldsymbol{\vartheta}} = \mathbf{V}_B\mathbf{B}^T\mathbf{G}_A(\mathbf{c} - \mathbf{A}\mathbf{Y})$$

The joint covariance matrix of $\hat{\boldsymbol{\beta}}$ and $\hat{\boldsymbol{\vartheta}}$ is:

$$\text{Cov} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\vartheta}} \end{bmatrix} = \begin{pmatrix} \mathbf{V} + \mathbf{V}\mathbf{A}^T\mathbf{G}_A(\mathbf{B}\mathbf{V}_B\mathbf{B}^T\mathbf{G}_A - \mathbf{I})\mathbf{A}\mathbf{V} & -\mathbf{V}\mathbf{A}^T\mathbf{G}_A\mathbf{B}\mathbf{V}_B \\ -\mathbf{V}_B\mathbf{V}^T\mathbf{G}_A\mathbf{A}\mathbf{V} & \mathbf{V}_B \end{pmatrix}$$

Data Reconciliation

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Multidimensional
Random Variable

Simple Regression

Multiple Regression

Data Reconciliation

Example (Continuation)

If the constraints do not contain unknown parameters, the following applies:

$$\hat{\beta} = \mathbf{Y} + \mathbf{V}\mathbf{A}^T\mathbf{G}_A(\mathbf{c} - \mathbf{A}\mathbf{Y}), \text{Cov}[\hat{\beta}] = \mathbf{V} - \mathbf{V}\mathbf{A}^T\mathbf{G}_A\mathbf{A}\mathbf{V}$$

The χ^2 statistic of the balance is defined by:

$$\chi^2 = (\mathbf{Y} - \hat{\beta})^T\mathbf{G}(\mathbf{Y} - \hat{\beta})$$

If \mathbf{Y} is normally distributed with covariance matrix $\mathbf{V} = \mathbf{G}^{-1}$, then χ^2 is χ^2 -distributed with $m - r$ degrees of freedom.

Data Reconciliation

Statistical Methods
of Data Analysis

W. Waltenberger

Introduction

Multidimensional
Random Variable

Simple Regression

Multiple Regression

Data Reconciliation

Example (balancing angles in triangle)

In a triangle, the angles $\beta = (\beta_1, \beta_2, \beta_3)$ are measured. Let the values in degrees be $\mathbf{Y} = (34.26, 86.07, 59.52)$, the measurement errors $\sigma_1 = 0.1, \sigma_2 = 0.08, \sigma_3 = 0.12$. The measured angles must obey the constraint $\beta_1 + \beta_2 + \beta_3 = 180$.

- $\mathbf{A} = (1, 1, 1), c = 180$, and $\mathbf{V} = \text{diag}(.1^2, .08^2, .12^2)$.
- Furthermore, $\mathbf{G}_A = (\mathbf{A}\mathbf{V}\mathbf{A}^T)^{-1} = 32.468$.
- Thus $\hat{\beta} = \mathbf{Y} + \mathbf{V}\mathbf{A}^T\mathbf{G}_A(c - \mathbf{A}\mathbf{Y}) = (34.31, 86.10, 59.59)$
- $\text{Cov}[\hat{\beta}] = \mathbf{V} - \mathbf{V}\mathbf{A}^T\mathbf{G}_A\mathbf{A}\mathbf{V} = 10^{-2} \cdot \begin{pmatrix} .68 & -.21 & -.47 \\ -.21 & .51 & -.30 \\ -.47 & -.30 & .77 \end{pmatrix}$.

All estimated values are negatively correlated.

- $\chi^2 = (\mathbf{Y} - \hat{\beta})^T \mathbf{G}(\mathbf{Y} - \hat{\beta}) = 0.846, p = 0.36$. The errors seem to be realistic.

Nonlinear Constraints

If the constraints are nonlinear, they can be written in the following general form:

$$h(\beta, \vartheta) = 0$$

First, h is linearized at appropriate point (β_0, ϑ_0) :

$$h(\beta, \vartheta) \approx h(\beta_0, \vartheta_0) + \mathbf{A}_0(\beta - \beta_0) + \mathbf{B}_0(\vartheta - \vartheta_0) = \mathbf{A}_0\beta + \mathbf{B}_0\vartheta - c_0$$

with

$$\mathbf{A}_0 = \frac{\partial h}{\partial \beta}, \mathbf{B}_0 = \frac{\partial h}{\partial \vartheta}, c_0 = \mathbf{A}_0\beta_0 + \mathbf{B}_0\vartheta_0 - h(\beta_0, \vartheta_0).$$

The estimation follows as in the linear case. Then h is estimated at the point $\beta_1, \vartheta_1 = \hat{\beta}, \hat{\vartheta}$ is re-linearized. It is repeated until the constraints are satisfied well enough.

- In Bayesian statistics probabilities are interpreted as rational assessments or degrees of belief about the true state of the world.
- Both data and unknown parameters of distributions are considered as random variables.
- Prior information about the unknown parameters is summarized by the **prior distribution**.
- The information contained in the data is used to update the information expressed by the prior distribution. Specifically, application of Bayes' theorem produces the posterior distribution of the parameters, conditional on the observations.
- The posterior distribution can be used for estimation of parameters, calculation of credible intervals, for testing and forecasting, for model choice etc.

- Choice of the prior introduces a subjective component into data analysis.
- This can have a noticeable effect in particular for small samples.
- There are ways of constructing priors that minimize this effect.
- For large samples the effect of the prior is usually negligible.
- In this case, Bayesian analysis gives approximately the same results as frequentist methods.
- The posterior contains more information than frequentist point and interval estimators.

- The **sample space** \mathcal{Y} is the set of all possible samples \mathbf{y} .
- The **parameter space** Θ is the set of all possible values of the parameters ϑ .
- The **prior density** $\pi(\vartheta)$ reflects our belief whether a value ϑ describes the true distribution of the data.
- The **likelihood function** $p(\mathbf{y}|\vartheta)$ gives the probability of observing data \mathbf{y} if ϑ is the true parameter.
- After observation of \mathbf{y} our belief about ϑ can be updated, by using Bayes' theorem to compute the **posterior density**:

$$p(\vartheta|\mathbf{y}) = \frac{p(\mathbf{y}|\vartheta)\pi(\vartheta)}{\int_{\Theta} p(\mathbf{y}|\vartheta)\pi(\vartheta) \, d\vartheta}$$

- The posterior distribution describes our belief about ϑ given the observation \mathbf{y} .
- If new data become available, the posterior can be used as again as the prior.
- If the normalizing integral cannot be computed analytically, one has to resort to numerical or Monte-Carlo methods.
- Common point estimators of ϑ are the **posterior mean**, the **posterior mode**, and the **posterior median** of $p(\vartheta|\mathbf{y})$.
- In addition, **credible intervals** and **HPD intervals** can be constructed from the posterior density.

- The choice of the prior can have a large effect for small samples.
- We distinguish between **informative** and **non-informative** priors.
- An informative prior describes actual information about ϑ . The information can be objective or subjective.
- A non-informative prior describes the absence of such information.
- In all cases the sensitivity of the result on the prior has to be studied.

- The prior does not have to be normalized, as the normalizing constant cancels out in Bayes' theorem.
- Priors that can be normalized are called **proper**; otherwise they are called **improper**.
- An improper prior **may** lead to a proper posterior.
- The choice of the prior is frequently based on computational convenience.
- For some types of likelihood functions there exist priors that give a posterior from the same family of distributions.
- Such priors are called **conjugate** priors.
- In a few cases a non-informative prior is also a conjugate prior.

- There are several proposals for choosing a non-informative prior:
 - Principle of **maximal entropy**
 - Invariance under parameter transformations: **Jeffrey's prior**
 - Minimal influence of the prior on the posterior: **Reference prior**
- For univariate ϑ Jeffrey's prior and Reference prior are identical in most cases; this is no longer true in the multivariate case.

- **Jeffrey's prior** is constructed such that it is invariant under a transformation of ϑ .
- Let $\tau = h(\vartheta)$ and $\pi_J(\vartheta)$ Jeffrey's prior in ϑ .
- The transformed prior in τ is equal to

$$\pi(\tau) = \pi_J(\vartheta) \left| \frac{d\vartheta}{d\tau} \right|$$

- The transformed Fisher information is equal to

$$I(\tau) = I(\vartheta) \left(\frac{d\vartheta}{d\tau} \right)^2$$

- Jeffrey's prior is therefore chosen as

$$\pi_J(\vartheta) \propto \sqrt{I(\vartheta)}$$

- We consider a Bernoulli experiment repeated n times with probability of success ϑ .
- The number Y of successes is then binomially distributed according to $\text{Bi}(n, \vartheta)$.
- We want to obtain a statement about the success probability ϑ from an observation y .
- To do this, we need an a-priori distribution of ϑ .
- The maximum entropy principle yields the uniform distribution $\text{Un}(0, 1) = \text{Be}(1, 1)$ as the a-priori distribution:

$$\pi(\vartheta) = I_{[0,1]}(\vartheta)$$

- The likelihood function is equal to

$$p(y|\vartheta) = \binom{n}{y} \vartheta^y (1 - \vartheta)^{n-y}$$

- Bayes' theorem provides the a-posteriori density:

$$p(\vartheta|y) \propto \vartheta^y (1 - \vartheta)^{n-y} I_{[0,1]}(\vartheta)$$

- Since the a-posteriori density is proportional to the density of the beta distribution $\text{Be}(y + 1, n - y + 1)$, it must be identical to it.
- The expected value of the a-posteriori distribution is equal to

$$E[\vartheta|y] = \frac{y + 1}{n + 2}$$

- The mode of the a-posteriori distribution is equal to

$$\hat{\vartheta} = \frac{y}{n}$$

and thus the maximum likelihood estimator of ϑ .

- The Fisher information of an observation is equal to

$$I(\vartheta) = \frac{1}{\vartheta(1-\vartheta)}$$

- Jeffrey's prior is thus $\text{Be}(0.5, 0.5)$.
- Bayes' theorem again provides the a-posteriori density:

$$p(\vartheta|y) \propto \vartheta^{y-0.5}(1-\vartheta)^{n-y-0.5}I_{[0,1]}(\vartheta)$$

- Since the a-posteriori density is proportional to the density of the beta distribution $\text{Be}(y+0.5, n-y+0.5)$, it must be identical to it.
- The expected value of the a-posteriori distribution is equal to

$$\mathbb{E}[\vartheta|y] = \frac{y+0.5}{n+1}$$

- The mode of the a-posteriori distribution is equal to

$$\hat{\vartheta} = \frac{y-0.5}{n-1}$$

- If prior information about ϑ is available, it can be included via a suitable a-priori density.
- It is computationally the simplest if the a-priori distribution is also a beta distribution.

- Let

$$\pi(\vartheta) = \frac{\vartheta^{a-1}(1-\vartheta)^{b-1}}{B(a,b)}$$

- Then the a-posteriori density is equal to

$$\begin{aligned} p(\vartheta|y) &\propto \vartheta^y(1-\vartheta)^{n-y}\vartheta^{a-1}(1-\vartheta)^{b-1} \\ &= \vartheta^{y+a-1}(1-\vartheta)^{n-y+b-1} \end{aligned}$$

- The a-posteriori distribution is again a beta distribution, namely $\text{Be}(y+a, n-y+b)$.

- Obviously, an a-priori beta distribution with a binomial likelihood function again gives an a-posteriori beta distribution.
- Therefore, the beta distribution is the **conjugate** a-priori distribution to the binomial distribution.
- The expected value of the a-posteriori distribution is equal to

$$E[\vartheta|y] = \frac{a + y}{a + b + n}$$

- The mode of the a-posteriori distribution is equal to

$$\hat{\vartheta} = \frac{a + y - 1}{a + b + n - 2}$$

- The expected value of the a-posteriori distribution can be written as a weighted average of a-priori information and data:

$$\begin{aligned} E[\vartheta|y] &= \frac{a + y}{a + b + n} = \frac{a + b}{a + b + n} \frac{a}{a + b} + \frac{n}{a + b + n} \frac{y}{n} \\ &= \frac{a + b}{a + b + n} \times \text{a-priori expectation} \\ &\quad + \frac{n}{a + b + n} \times \text{average of data} \end{aligned}$$

- a and b can be interpreted as “a-priori data”:

a number of successes a-priori

b number of failures a-priori

$a + b$ number of attempts a-priori

- If the number of trials a-priori is set equal to 0, we get **Haldane's prior**:

$$\pi_H = \frac{1}{\vartheta(1 - \vartheta)}$$

- Haldane's prior can be interpreted as $\text{Be}(0, 0)$, but is improper.
- The a-posteriori mean is then equal to the ML estimator.
- Paradox: The a-priori distribution without any prior information gives the values $\vartheta = 0$ and $\vartheta = 1$ the highest probability!

- We now want to construct ranges of the parameter space Θ that contain the true value of ϑ with a certain confidence $1 - \alpha$.
- Such a range is called a **credible (or credibility) region**. It is usually an interval (credible interval).
- The simplest construction of a credible interval $[\vartheta_1(y), \vartheta_2(y)]$ uses the quantiles of the a-posteriori distribution.
- The symmetric credible interval is:

$$\vartheta_1(y) = q_{\alpha/2}, \quad \vartheta_2(y) = q_{1-\alpha/2}$$

where q_p is the p -quantile of the a-posteriori distribution $p(\vartheta|y)$.

- The symmetric credible interval contains values of ϑ that have lower a-posteriori probabilities than some points outside the interval.
- A range in which all values of ϑ have higher a-posteriori probability than all values outside the range is called a high-posterior density range, or **HPD** range for short.
- If the a-posteriori density is unimodal, the HPD range is an HPD interval.
- In this case, the ϑ_1, ϑ_2 bounds of the HPD interval are obtained as the solution of the system of equations:

$$\begin{aligned}p(\vartheta_2|y) - p(\vartheta_1|y) &= 0 \\ P(\vartheta_2|y) - P(\vartheta_1|y) &= 1 - \alpha\end{aligned}$$

Here $P(\vartheta|y)$ is the a-posteriori distribution function.

Example

An alternative trial is repeated $n = 20$ times and does not yield a single success ($k = 0$). What can be said about the probability of success ϑ ?

- With a-priori density $\pi(\vartheta) = 1$, the a-posteriori distribution is $\text{Be}(1, 21)$. The mode is equal to 0, and the expected value is equal to 0.0455. The HPD interval with $1 - \alpha = 0.95$ is equal to $[0, 0.1329]$.
- With Jeffrey's prior, the a-posteriori distribution is $\text{Be}(0.5, 20.5)$. The mode is equal to 0, and the expected value is equal to 0.0238. The HPD interval with $1 - \alpha = 0.95$ is equal to $[0, 0.0905]$.
- If it is known that ϑ is rather small, e.g. $\text{Be}(0.5, 5)$ can be chosen as a-priori distribution. The a-posteriori distribution is then $\text{Be}(0.5, 25)$. The mode is equal to 0, the expected value is equal to 0.0196, and the HPD interval is equal to $[0, 0.0747]$.

- Observing a Poisson process yields the values $\mathbf{y} = y_1, \dots, y_n$.
- We want to obtain an estimate of the intensity λ of the process from the data.
- The likelihood function is:

$$p(\mathbf{y}|\lambda) = \prod_{i=1}^n \frac{\lambda^{y_i} e^{-\lambda}}{y_i!} \propto \lambda^{\sum y_i} e^{-n\lambda}$$

- It depends only on $s = \sum y_i$.
- As non-informative a-priori distributions we may consider:
 - The improper density $\pi(\lambda) = 1$
 - Jeffrey's prior $\pi_J(\lambda) = \lambda^{-1/2}$, also improper

- With $\pi(\lambda) = 1$, the a-posteriori density is proportional to the likelihood function:

$$p(\lambda|s) \propto \lambda^s e^{-n\lambda}$$

- Since the a-posteriori density is proportional to the density of the gamma distribution $\text{Ga}(s+1, 1/n)$, it must be identical to it:

$$p(\lambda|s) = \frac{\lambda^s e^{-n\lambda}}{n^{-(s+1)} \Gamma(s+1)}$$

- The expected value of the a-posteriori distribution is equal to:

$$E[\lambda|s] = \frac{s+1}{n}$$

- The mode of the a-posteriori distribution is equal to

$$\hat{\lambda} = \frac{s}{n}$$

and thus the maximum likelihood estimator of λ .

- If prior information about λ is available, it can be included by a suitable a-priori density.
- It is computationally the simplest if the a-priori distribution is a gamma distribution.

- Let

$$\pi(\lambda) = \frac{b^a \lambda^{a-1} e^{-b\lambda}}{\Gamma(a)}$$

This is the density of the gamma distribution $\text{Ga}(a, 1/b)$.

- Then the a-posteriori density is equal to

$$\begin{aligned} p(\lambda|s) &\propto \lambda^s e^{-n\lambda} \lambda^{a-1} e^{-b\lambda} \\ &= \lambda^{s+a-1} e^{-(b+n)\lambda} \end{aligned}$$

- The a-posteriori distribution is the gamma distribution $\text{Ga}(a + s, 1/(b + n))$. Thus, the gamma distribution is conjugate to the Poisson distribution.

- The expected value of the a-posteriori distribution is equal to

$$E[\lambda|s] = \frac{a + s}{b + n}$$

- The mode of the a-posteriori distribution is equal to

$$\hat{\lambda} = \frac{a + s - 1}{b + n}$$

- The expected value of the a-posteriori distribution can be written as a weighted average of a-priori information and data:

$$\begin{aligned} E[\lambda|s] &= \frac{a + s}{b + n} = \frac{b}{b + n} \frac{a}{b} + \frac{n}{b + n} \frac{s}{n} \\ &= \frac{b}{b + n} \times \text{a-priori expectation} \\ &\quad + \frac{n}{b + n} \times \text{average of data} \end{aligned}$$

- Credible intervals $[\lambda_1(s), \lambda_2(s)]$ can be easily constructed using the quantiles of the a-posteriori gamma distribution.
- The symmetric credible interval is equal to

$$[\gamma_{\alpha/2; a+s, 1/(b+n)}, \gamma_{1-\alpha/2; a+s, 1/(b+n)}]$$

- The one-sided credible intervals are

$$[0, \gamma_{\alpha; a+s, 1/(b+n)}] \quad \text{and} \quad [\gamma_{\alpha; a+s, 1/(b+n)}, \infty]$$

- HPD ranges can be determined using numerical methods.

Example

You measure the background radiation in a laboratory over a period of 20 seconds. The count values are

6, 2, 6, 1, 6, 8, 5, 3, 8, 4, 2, 5, 7, 8, 5, 4, 7, 9, 4, 4

Their sum is equal to $s = 104$. Using Jeffrey's prior, the a-posteriori distribution is the gamma distribution $\text{Ga}(104.5, 0.05)$. Its expectation is 5.225, and its mode is 5.1750. The symmetric credible interval at $1 - \alpha = 0.95$ is $[4.2714, 6.2733]$, the HPD interval is $[4.2403, 6.2379]$. Since the distribution is almost symmetric, the two intervals are practically the same length.

Example

An observation from a Poisson distribution has the value $k = 0$. What can be said about the mean λ ?

- With a-priori density $\pi(\lambda) = 1$, the a-posteriori distribution is $\text{Ga}(1, 1)$. The mode is 0, and the mean is 1. The HPD interval with $1 - \alpha = 0.95$ is $[0, 2.9957]$.
- With Jeffrey's prior, the a-posteriori distribution is $\text{Ga}(0.5, 1)$. The mode is 0, and the mean is 0.5. The HPD interval with $1 - \alpha = 0.95$ is $[0, 1.9207]$.
- If it is known that λ is significantly smaller than 1, for example, $\text{Ga}(0.5, 0.5)$ can be chosen as the a-priori distribution. The a-posteriori distribution is then $\text{Ga}(0.5, 0.6667)$. The mode is 0, the mean is 0.3333, the HPD interval is $[0, 1.2805]$.
- The likelihood estimator of λ is 0.
- The lower confidence interval is $[0, 2.9957]$, so it is identical to the HPD interval with improper a-priori density.

- We consider a normally distributed sample $\mathbf{y} = (y_1, \dots, y_n)$.
- We want to obtain an estimate of the mean and variance of the distribution from which the data are drawn.
- We first assume that the variance σ^2 is known.
- Then the likelihood function is:

$$p(\mathbf{y}|\mu, \sigma^2) = \prod_{i=1}^n \frac{1}{\sqrt{2\pi}\sigma} \exp \left[-\frac{(y_i - \mu)^2}{2\sigma^2} \right]$$

- In the absence of any prior information about the actual value of μ , we choose the improper a-priori density $\pi(\mu) = 1$, which is also Jeffrey's prior.

- If the variance σ^2 is unknown, we need a joint a-priori density for μ and σ^2 .
- The calculation is simpler if we use the precision $\zeta = 1/\sigma^2$ instead of the variance σ^2 .
- A possible choice is the improper a-priori density

$$\pi(\mu, \zeta) = \frac{1}{\zeta}$$

- Then:

$$\begin{aligned} p(\mu, \zeta | \mathbf{y}) &\propto \frac{1}{\zeta} \prod_{i=1}^n \sqrt{\zeta} \exp \left[-\frac{\zeta}{2} \sum_{i=1}^n (y_i - \mu)^2 \right] \\ &\propto \zeta^{n/2-1} \exp \left[-\frac{\zeta}{2} \sum_{i=1}^n (y_i - \mu)^2 \right] \end{aligned}$$

- Integration over μ gives the a-posteriori density of ζ :

$$\begin{aligned} p(\zeta|\mathbf{y}) &\propto \int \zeta^{n/2-1} \exp \left[-\frac{\zeta}{2} \sum_{i=1}^n (y_i - \mu)^2 \right] d\mu \\ &\propto \zeta^{(n-3)/2} \exp \left[-\frac{\zeta}{2} \sum_{i=1}^n (y_i - \bar{y})^2 \right] \end{aligned}$$

- ζ is therefore a-posteriori gamma distributed according to $\text{Ga}((n-1)/2, 2/\sum (y_i - \bar{y})^2)$. Because of

$$\sum (y_i - \bar{y})^2 = \sum y_i^2 - n\bar{y}^2$$

the distribution depends only on $s_1 = \sum y_i$ and $s_2 = \sum y_i^2$ i.e. on the sample mean \bar{y} and the sample variance S^2 .

- We consider an exponentially distributed sample $\mathbf{y} = (y_1, \dots, y_n)$, $n > 1$.
- We want to obtain an estimate of the mean τ of the exponential distribution from which the data are drawn.
- The likelihood function is:

$$p(\mathbf{y}|\tau) = \prod_{i=1}^n \frac{1}{\tau} \exp\left(-\frac{y_i}{\tau}\right) = \frac{1}{\tau^n} \exp\left(-\frac{\sum y_i}{\tau}\right)$$

- The Fisher information is equal to $I_\tau = n/\tau^2$; Jeffrey's prior is therefore $\pi_J(\tau) = \tau^{-1}$ and hence improper.
- The a-posteriori distribution is then proportional to

$$p(\tau|\mathbf{y}) \propto \frac{1}{\tau^{n+1}} \exp\left(-\frac{\sum y_i}{\tau}\right) = \frac{1}{\tau^{n+1}} \exp\left(-\frac{s}{\tau}\right)$$

- The likelihood function can also be parameterized with the mean rate λ :

$$p(\mathbf{y}|\lambda) = \prod_{i=1}^n \lambda \exp(-\lambda y_i) = \lambda^n \exp\left(-\lambda \sum y_i\right) = \lambda^n \exp(-\lambda s)$$

- Jeffrey's prior is $\pi_J(\lambda) = \lambda^{-1}$.
- The a-posteriori distribution is then proportional to

$$p(\lambda|\mathbf{y}) \propto \lambda^{n-1} \exp(-\lambda s)$$

- The a-posteriori distribution is therefore the gamma distribution $\text{Ga}(n, 1/s)$ with mean n/s and mode $(n-1)/s$. The mean is equal to the maximum likelihood estimator of λ .
- The gamma distribution is also the conjugate a-priori distribution.

- The sequence X_0, X_1, \dots of discrete random variables is called a **discrete Markov chain** if the **Markov property** holds:

$$P(X_{n+1} = j | X_1 = i_1, \dots, X_n = i_n) = P(X_{n+1} = j | X_n = i_n)$$

- The transition probabilities are calculated in a **transition matrix** $p_{ij}^{(n)}$, with:

$$p_{ij}^{(n)} = P(X_{n+1} = j | X_n = i)$$

$p_{ij}^{(n)}$ is an **stochastic matrix**: the row sums are 1.

- In a **time homogeneous** Markov chain, $p_{ij}^{(n)} = p_{ij}$ holds for all n .
- Let $\pi^{(0)}$ be the density of X_0 . Then the density of X_n is.

$$\pi^{(n)} = \pi^{(0)} p_{ij}^{(n)}$$

- Under certain circumstances (the chain must be irreducible, all states must be positively recurrent), a temporally homogeneous Markov chain has a **stationary distribution** π , with

$$\pi = \pi p_{ij}$$

- Obviously, π is a left eigenvector of p_{ij} with the eigenvalue $\lambda = 1$.

Example

Simple weather model. States: sunny=1, rainy=2. Transition matrix:

$$p_{ij} = \begin{pmatrix} 0.9 & 0.1 \\ 0.4 & 0.6 \end{pmatrix}$$

Markov Chain Monte
Carlo

- A discrete Markov chain is called **reversible** if the condition of **detailed balance** holds, i.e. if there is a distribution p_{ij} for which holds:

$$\pi_i p_{ij}^{(n)} = \pi_j p_{ji}^{(n)}$$

- In that case p_{ij} is a stationary distribution of the chain.
- For **continuous** random variables X_i , the transition matrix is replaced by a **transition kernel** $q(x, y)$ with:

$$\int q(x, y) dy = 1$$

- If at time n the state of the chain is equal to x , then the State y at time $n + 1$ is given by $q(x, y)$.

Markov Chain Monte
Carlo

- **Markov Chain Monte Carlo (MCMC)** proceeds in reverse: given a target distribution $\pi(x)$, we look for a transition kernel $q(x, y)$ that has $\pi(x)$ as its stationary distribution.
- It is in general not possible to find such a kernel explicitly. A convenient solution is the **Metropolis–Hastings** algorithm.
- Assume that for some x, y

$$\pi(x)q(x, y) > \pi(y)q(y, x)$$

Then the chain evolves from x to y more often than from y to x .

- To correct this, the frequency of evolutions from x to y is reduced by introducing an **acceptance probability** $\alpha(x, y) < 1$.

- From the detailed balance condition we get

$$\alpha(x, y) = \min \left[1, \frac{\pi(y)q(y, x)}{\pi(x)q(x, y)} \right]$$

- $\alpha(x, y)$ can be calculated **without knowledge of the normalization constant of $\pi(x)$** !

The Metropolis–Hastings Algorithm

- Generate a starting value x_0 .
- For $i=1, \dots, N$:
 - Generate a proposal value y from $q(x_{i-1}, y)$ and u from $\text{Un}(0, 1)$.
 - If $u \leq \alpha(x_{i-1}, y)$, set $x_i = y$, otherwise $x_i = x_{i-1}$.
- Discard the first n links of the chain („burn-in”).

Markov Chain Monte
Carlo

- The M–H algorithm can be used to draw from densities with unknown normalization, such as posteriori densities.
- If $q(x, y) = q(y, x)$, then the acceptance probability is

$$\alpha(x, y) = \min \left[1, \frac{\pi(y)}{\pi(x)} \right]$$

- If $\pi(y) > \pi(x)$, then take the proposed step; otherwise take the step with probability $\pi(y)/\pi(x)$. This is the basis of **optimization by "simulated annealing"**.
- If $q(x, y) = g(y - x)$, then the chain is a **random walk**, as $y = x + z$, z being the noise term with a distribution $g(z)$. If $g(x)$ is symmetric, the probability of acceptance reduces again as above.

- In case $q(x, y) = p(y)$ does not depend on x , the algorithm is also called **Independence Sampler**, and $p(y)$ is called the **Suggestion Density**. The acceptance probability is

$$\alpha(x, y) = \min \left[1, \frac{\pi(y)p(x)}{\pi(x)p(y)} \right]$$
